**Parent topic:** Setting up a remote Oracle database on Windows for a stand-alone production server  
**Previous topic:** Installing Oracle  
**Next topic:** Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal.

For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:
  - $\text{db\_block\_size} = 8192$ bytes
  - $\text{db\_cache\_size} = 307,200$ bytes
  - $\text{db\_files} = 1024$ files
  - $\text{log\_buffer} = 65536$ bytes
  - $\text{open\_cursors} = 1500$ cursors
  - $\text{pga\_aggregate\_target} = 204,800$ bytes
  - $\text{pre\_page\_sga} = \text{true}$
  - $\text{processes} = 300$ processes
  - $\text{shared\_pool\_size} = 204,800$ bytes

  **Note:** If you are using IBM Java Content Repository, the $\text{open\_cursors}$ value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the $\text{parallel\_max\_servers}$ to 1200.

- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:
  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.
  - **EXACT**
- When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

- **Prerequisites**
  - Installing Oracle
  - Creating users

**Parent topic:** Setting up a remote Oracle database on Windows for a stand-alone production server  
**Previous topic:** Creating users  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`

  - If you are using a remote database, enter the values for the remote server.
  - Use a forward slash (/) instead of a backslash (\).
  - There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
  - The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
  - Depending on which database domain has to be configured, replace `dbdomain` with:
    - `release`
    - `customization`
    - `community`
    - `jcr`
    - `feedback`
    - `likeminds`

  - The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
    - `dbdomain.DbType`
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.

   A. For dbdomainDbType, type oracle.
   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomain_DbUrl property.
   C. For dbdomainDbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomainDbName should be the same value used for the dbdomain.dbSchema

      Restriction: The value for dbdomainDbSchema must equal the value for dbdomainDbUser.
   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:

      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback

   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note:

      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:

         jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

   F. For dbdomainDbUser, type the user ID for the database administrator. Restriction: The value for dbdomainDbUser must equal the value for dbdomainDbSchema.
G. For dbdomain..DbPassword, type the password for the database administrator.

H. For dbdomain=DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.

I. For dbdomain=DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.

J. For dbdomain.DbHome, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For source.domainDbType, type of the database you are currently configured to use. The value for source.domainDbType is Derby by default.

B. For source.domainDbName, type the name of the database domain you are currently using.

C. For source.domainDbSchema, type current schema identifier for objects within the database for this domain.

D. For source.domain.DataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For source.domainDbUrl, type the url currently used to access your database.

F. For source.domainDbUser, type the name of the user accessing this database.

G. For source.domainDbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplcDbType.properties.

A. For oracle.DbDriver, type the name of the class that SqlProcessor uses to import SQL files.

B. For oracle.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For oracle.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Setting up a remote Oracle database on Windows for a stand-alone production server  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases
This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces.

**Prerequisites**
- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties

As an alternative to automatically setting up the database, you can manually set up your database by referring to the link in the related tasks section of this topic.

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.
2. Change to the directory `wp_profile_root/ConfigEngine`
3. To create the database users, type the following command:

   ```
   ConfigEngine.bat setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   ```
   <WP_root>/base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql
   ```

**Parent topic:** Setting up a remote Oracle database on Windows for a stand-alone production server

**Previous topic:** Modifying database properties

**Next topic:** Windows stand-alone server: Creating JCR table spaces

**Related tasks**
Manually creating users and granting privileges for Oracle
Windows stand-alone server: Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

**Prerequisites**
- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties
- Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

**Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

```
cREATE TABLESPACE ICMLFQ32 DATAFILE '&dbpath./&jcrdb./data/ICMLFQ32_01.dbf' SIZE 300M REUSE AUTOEXTEND NEXT 10M MAXSIZE UNLIMITED EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
CREATE TABLESPACE ICMLNF32 DATAFILE '&dbpath./&jcrdb./data/ICMLNF32_01.dbf' SIZE 25M REUSE AUTOEXTEND NEXT 10M MAXSIZE UNLIMITED EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
CREATE TABLESPACE ICMVFQ04 DATAFILE '&dbpath./&jcrdb./data/ICMVFQ04_01.dbf' SIZE 25M REUSE AUTOEXTEND NEXT 10M MAXSIZE UNLIMITED EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
CREATE TABLESPACE ICMSFQ04 DATAFILE '&dbpath./&jcrdb./data/ICMSFQ04_01.dbf' SIZE 150M REUSE AUTOEXTEND NEXT 10M MAXSIZE UNLIMITED EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
CREATE TABLESPACE ICMLSNDX DATAFILE '&dbpath./&jcrdb./index/ICMLSNDX_01.dbf' SIZE 10M REUSE AUTOEXTEND NEXT 10M MAXSIZE UNLIMITED EXTENT MANAGEMENT LOCAL AUTOALLOCATE;
```

A. Set the size, autoextend, and maxsize values according to your environment. For example, you may want to change the maxsize to a set value rather than UNLIMITED.

B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.

C. Refer to the Oracle command reference for more information about using the `create tablespaces` command.

**Parent topic:** Setting up a remote Oracle database on Windows for a stand-alone production server

**Previous topic:** Setting up databases

**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the \wp_profile_root\PortalServer\config\tablespaces\dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Windows stand-alone server: Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file \wp_profile_root\PortalServer\config\tablespaces\dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - \dbdomain.table_name.tablespace
   - \dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, \dbdomain\ can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword \TABLESPACE and a space. For example: \community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close \dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
Configuring WebSphere Portal to use Oracle

View information on manually transferring data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Windows stand-alone server: Creating JCR table spaces

**Tips:**

- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`.
2. Enter the following commands to validate configuration properties.
   ```plaintext
   ConfigEngine.bat validate-database-driver
   ConfigEngine.bat validate-database-connection
   ```
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>stopServer.bat server1 -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>
5. Transfer the database:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root\ConfigEngine`.

   B. Enter the following command:

       ```
       ConfigEngine.bat database-transfer -DWasPassword=password
       ```

       **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

       ```
       ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
       ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

       If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

   ```
   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
   ```

7. Change to the directory `wp_profile_root\bin`.

8. Enter the following command to start the WebSphere Portal server:

   ```
   startServer.bat WebSphere_Portal -username admin_userid -password admin_password
   ```

---

**Previous topic:** Assigning custom table spaces
Setting up a remote Oracle RAC database on Windows for a stand alone production server

Setting up the Oracle RAC database includes creating user IDs and databases on a remote server. A task is provided to assist with creating the users. Before you can use the task, you must modify properties files.

1. **Installing Oracle RAC**
   View information on how to install Oracle RAC for use with WebSphere Portal.

2. **Create users**
   View the steps to set up users for Oracle RAC to work with WebSphere Portal.

3. **Creating databases**
   View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal.

4. **Modifying database properties**
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. **Setting up databases**
   This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces. As an alternative to automatically setting up the database, you can manually set up your database.

6. **Windows stand-alone server: Creating JCR table spaces**
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. **Optional: Assigning custom table spaces**
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. **Configure WebSphere Portal to use Oracle RAC**
   View information on manually transferring data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

**Parent topic:** Setting up a database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:
- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon (GSD), oracle listeners, and agents.
  - `$ gsdctl start`
  - `$ lsnrctl start`
  - `$ agentctl start`

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Setting up a remote Oracle RAC database on Windows for a stand alone production server

Next topic: Create users

Related tasks
Manually creating users and granting privileges for Oracle
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:
- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**
- Installing Oracle RAC

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects:

   ```sql
   SQL> create user username identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   ```

   Tip: Balance the storage of user objects among tablespaces to prevent running out of space with overuse of `user_tablespace`. Also consider increasing the size of `user_tablespace` when handling a high volume of users.

2. Log in by entering the command `sqlplus` in SQL*Plus:

3. Enter the command `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

4. Create the WebSphere Portal user `dbdomain.DBUser`, where `dbdomain` is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults:

   ```sql
   SQL> create user releaseusr identified by password;
   SQL> create user communityusr identified by password;
   SQL> create user customizationusr identified by password;
   SQL> create user jcr identified by password;
   ```

5. Connect to the content database by entering the command `SQL> connect`.

6. Enter the following, where `username` is an existing administrative user in the database.

   ```sql
   user-name: username/password@dbname
   ```

   For example, `system/manager@jcrdb` will log the administrative user system with a password of manager into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the `jcr` user, grant all necessary privileges. If you do not grant privileges, you will receive the error `ICMADMIN lacks CREATE SESSION Privilege logon denied`. 

   ```sql
   SQL> connect username/password@dbname
   ```
when you try to connect with the \texttt{jcruser}: \texttt{SQL} > create user \texttt{jcr} identified by \texttt{password} default tablespace users temporary tablespace temp;

8. Connect to the Feedback database:
   A. Enter the following command: \texttt{SQL} > connect
   B. Enter \texttt{user-name}: \texttt{username/password@dbname} where \texttt{username} is an existing administrative user in the database.
      For example, system/manager@fdbkdb will log the administrative user system with a password of manager into the fdbkdb database.

9. Create the Feedback user: \texttt{SQL} > create user \texttt{feedback} identified by \texttt{password} default tablespace users temporary tablespace temp;

10. Connect to the LikeMinds database: \texttt{SQL} > connect
11. Enter \texttt{user-name}: \texttt{username/password@dbname}, where \texttt{username} is an existing administrative user in the database. For example, system/manager@lmdb will log the administrative user system with a password of manager into the lmdb database.
12. Create the LikeMinds user: \texttt{SQL} > create user \texttt{lmdbusr} identified by \texttt{password} default tablespace users temporary tablespace temp;
13. Log out of the command line tool using the command \texttt{SQL} > exit.

\textbf{Parent topic:} Setting up a remote Oracle RAC database on Windows for a stand alone production server  
\textbf{Previous topic:} Installing Oracle RAC  
\textbf{Next topic:} Creating databases
Creating databases

View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal.

When creating Oracle RAC databases for use with WebSphere Portal, you should consider the following information:

- The Oracle RAC databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle RAC server will be remote or local to the WebSphere Portal installation.
- If using an earlier version of Oracle RAC (9i or earlier), ensure that Oracle RAC JVM is also installed.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle RAC database in order for WebSphere Portal to communicate with the IBM Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes are:

  - `db_block_size = 8192` bytes
  - `db_cache_size = 314,572,800` bytes
  - `db_files = 1024` files
  - `log_buffer = 65536` bytes
  - `open_cursors = 1500` cursors
  - `pga_aggregate_target = 209,715,200` bytes
  - `pre_page_sga = true`
  - `processes = 300` processes
  - `shared_pool_size = 209,715,200` bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the IBM Java Content Repository schema.

**Prerequisites**
- Installing Oracle RAC
- Create users

- **Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server
- **Previous topic:** Create users
- **Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release_DbName`, `jcr_DbName`, `feedback_DbName`, and `likeminds_DbName`. For example:
  - `release_DbName=release`
  - `jcr_DbName=jcrdb`
  - `feedback_DbName=fdbkdb`
  - `likeminds_DbName=lmdb`
  - `community_DbName=commdb`
  - `customization_DbName=custdb`
- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - `dbdomainDbType`
- **dbdomain.DbName**
- **dbdomain.DbUrl**
- **dbdomain.DbSchema**

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If **DbUser**, **DbUrl**, and **DbPassword** are not the same across domains, the value for **DataSourceName** must differ from the **DataSourceName** of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.

   A. For **dbdomainDbType**, type **oracle**.

   B. For **dbdomainDbName**, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the **dbdomainDbUrl** property.

   C. For **dbdomainDbSchema**, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The **dbdomain_DbName** should be the same value used for the **dbdomain_DbSchema**

      **Restriction:** The value for **dbdomain_DbSchema** must equal the value for **dbdomain_DbUser**.

   D. For **dbdomainDataSourceName**, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback

   E. For **dbdomainDbUrl**, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:**
      - The database element of this value should match the value of **DbName**.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        ```
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME.
        ```
      When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

   F. For **dbdomainDbUser**, type the user ID for the database administrator. **Restriction:** The value for **dbdomainDbUser** must equal the value for **dbdomainDbSchema**.
G. For `dbdomain.DbPassword`, type the password for the database administrator.
H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.
I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.
J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.
   A. For `source.domain.DbType`, type the database you are currently configured to use. The value for `source.domain.DbType` is Derby by default.
   B. For `source.domain.DbName`, type the name of the database domain you are currently using.
   C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.
   D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
   E. For `source.domain.DbUrl`, type the url currently used to access your database.
   F. For `source.domain.DbUser`, type the name of the user accessing this database.
   G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.
   A. For `oracle.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.
   B. For `oracle.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
   C. For `oracle.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.
   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces. As an alternative to automatically setting up the database, you can manually set up your database.

Before you begin, ensure that the following prerequisites are met:

- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

**Prequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root\ConfigEngine`

3. To create the database users, type the following command:

   ```bash
   ConfigEngine.bat setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`

---

**Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server

**Previous topic:** Modifying database properties

**Next topic:** Windows stand-alone server: Creating JCR table spaces

**Related tasks**

Manually creating users and granting privileges for Oracle
Windows stand-alone server: Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```
   create tablespace ICMLFQ32 datafile '/&dbpath./&jcrdb./data/&jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '/&dbpath./&jcrdb./data/&jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '/&dbpath./&jcrdb./data/&jcrdb._ICMVFQ04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '/&dbpath./&jcrdb./data/&jcrdb._ICMSFQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '/&dbpath./&jcrdb./index/&jcrdb._ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   
   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.
   ```

**Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server

**Previous topic:** Setting up databases

**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root` /PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Windows stand-alone server: Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `TABLESPACE` and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`
   
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
UNIX: `.ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server

**Previous topic:** Windows stand-alone server: Creating JCR table spaces

**Next topic:** Configure WebSphere Portal to use Oracle RAC
**Configure WebSphere Portal to use Oracle RAC**

View information on manually transferring data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

*Ensure that the following prerequisites are met:*

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**Prerequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Windows stand-alone server: Creating JCR table spaces

**Tips:**

- If you are transferring from Oracle, the `open_cursor` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:

  `jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521)) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE SERVICENAME)))`.

- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`. 
2. Enter the following commands to validate configuration properties.
   ```bash
   ConfigEngine.bat validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ConfigEngine.bat validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.

4. Stop both WebSphere Application Server and the WebSphere Portal server:
   ```bash
   Option                        Description
   WebSphere Application Server  stopServer.bat server1 -username admin_userid -password admin_password
   WebSphere Portal              stopServer.bat WebSphere_Portal -username admin_userid -password admin_password
   ```

5. Transfer the database:
   ```bash
   Option                        Description
   WebSphere Application Server  ConfigEngine.bat database-transfer -DWasPassword=password
   WebSphere Portal              ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```
   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:
   ```sql
   SQL> execute dbms_stats.gather_schema_stats(ownname=>'jcr', cascade=>TRUE);
   ```

7. Specify the JDBC URL to connect to the cluster:
   ```sql
  jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))(ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME))
   ```
   **Note:** To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   ```bash
   ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```

8. Change to the directory `wp_profile_root\bin`.
9. Enter the following command to start the WebSphere Portal server:
   ```bash
   startServer.bat WebSphere_Portal
   ```

**Parent topic:** Setting up a remote Oracle RAC database on Windows for a stand alone production server

**Previous topic:** Assigning custom table spaces
Setting up a remote SQL Server database on Windows for a stand-alone production server

To setup a remote Microsoft SQL Server Enterprise Edition database, create user IDs and databases on a remote server. Tasks are provided to assist with creating the user IDs and the databases. Before you can use the tasks, you must modify properties files.

1. Installing SQL Server
   View the steps to install SQL Server for use with WebSphere Portal.

2. Modifying database properties
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

3. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

   The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

5. Configuring WebSphere Portal to use SQL Server 2005
   View information on manually transferring data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Setting up a database
Installing SQL Server

View the steps to install SQL Server for use with WebSphere Portal.

Before you begin this task, complete the following prerequisites:

- You should have completed reviewing the Planning for SQL Server topic.
- You must install SQL Server separately from WebSphere Portal.
- WebSphere Portal requires either the DataDirect Connect for JDBC 3.7 JDBC driver or the Microsoft SQL Server JDBC Driver.
- You can obtain the DataDirect Driver from DataDirect Technologies. The JDBC driver consists of two parts: the JDBC driver libraries and JTA libraries. The JDBC driver libraries must be put on the WebSphere Portal system, while the JTA libraries are intended for SQL Server.
- You can obtain the Microsoft SQL Server JDBC Driver from Microsoft. See the Microsoft SQL Server product documentation for installation details.

The following section provides instructions for installing SQL Server for use with IBM® WebSphere® Application Server and WebSphere Portal. These steps are the same for both the DataDirect and Microsoft drivers unless noted.

1. Install SQL Server and all required patches.
2. Select the authentication mode for this installation:
   - Windows Authentication Mode
   - Mixed Mode (Windows Authentication and SQL Server Authentication)
     Either authentication mode allows the user who is specified as the database administrator in the wkplc_comp.properties file to log in to the SQL server. Mixed Mode authentication allows either a Windows user or a SQL server user, or both, to log in to the SQL Server.
3. In the SQL Server Setup panel, **Components to Install**, select the following components, which are required services for WebSphere Portal:
   - **SQL Server Database Services**
     - **Integration Services** The option Integration Services, creates the directory DTS/Binn, where you will need to copy files when you install Microsoft SQL Server JDBC drivers and enable XA connections.
4. Complete the installation using SQL Server documentation as a guide.
5. Enable TCP/IP connectivity in the **SQL Server Configuration Manager**.
6. Install the JDBC driver using one of these methods:
   - Installing DataDirect Connect for JDBC drivers on UNIX
   - Installing DataDirect Connect for JDBC drivers on Windows
   - Installing Microsoft SQL Server JDBC drivers and enabling XA connections
7. Network the connections for MSDTC in the Windows Component Services as described in Microsoft Help and Support.
8. Start SQL Server.

**Installing DataDirect Connect for JDBC drivers on UNIX**

1. Purchase and download DataDirect Connect for JDBC and save file 360connectjdbc.jar in a temporary work directory.
2. To create the required files, run the following command from the directory that contains 360connectjdbc.jar:

```
jar -xvf 360connectjdbc.jar
```
3. Run `./Installer.sh` in the same directory.
4. When installation is complete, change directory to `/installation/lib`, where `installation` is the directory in which you installed the DataDirect Connect for JDBC drivers.
5. Run the following command to change the permissions on the JAR files in the `installation/lib` directory:

```
chmod 777 *.jar
```
6. Change the ownership and group of these files by running the following commands in the `installation/lib` directory:

```
chgrp system_grp *.jar
chown root *.jar
```
Where `system_grp` is the system group as labeled by your operating system.

### Installing DataDirect Connect for JDBC drivers on Windows
1. Purchase and download DataDirect Connect for JDBC and save file `360connectjdbc.jar` in a temporary work directory.
2. To create the required files, run the following command from the directory that contains 360connectjdbc.jar:

```
jar -xvf 360connectjdbc.jar
```
3. Run `Installer.bat` in the same directory.

### Installing Microsoft SQL Server JDBC drivers and enabling XA connections
1. Download and install the Microsoft SQL Server JDBC driver.
2. Copy file `sqljdbc_xa.dll` from the `xa` subdirectory to the `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll` directory of the SQL Server installation.
3. Start the database server.
4. Ensure that the Distributed Transaction Coordinator has been started. The status can be verified in the list of services in the Computer Management console.
5. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.
6. Select `File > Open > File` and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.
7. Execute the script by selecting `Query > Execute.Note: Any warnings that appear in the messages section of the application window that say that stored procedures cannot be found can be safely ignored.
8. For Microsoft SQL Server JDBC drivers: If you are running Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003, refer to the Registry Entries Are Required for XA Transaction Support document for information on a new security constraint and how to set SQL Server on Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003. Create a additional value in the Windows registry for WebSphere Portal by following these steps:
   A. Open the Windows Registry Editor (regedit) and navigate to the element
      
      ```
      HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XADLL
      ```
   B. From the menu bar, select `Edit > New > String Value` to create a new parameter named `sqljdbc_xa.dll` in that element.
   C. Change the value of the new parameter to the location of the `sqljdbc_xa.dll` file copied in Step 2 above, for example:
      
      ```
      C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll
      ```

### Enable XA Transactions In Windows Component Services
1. From your Windows desktop, follow these steps:
2. Click `Start > Settings > Administrative Tools > Component Services.`
3. Expand the tree view to locate the computer where you want to turn on support for XA transactions (for example, My Computer).
4. Display the context menu for the computer name and click Properties.
5. Click Options and tune the Transaction Timeout that suits your environment. (The recommended minimum is 180 seconds).
6. Click MSDTC and click Security Configuration.
7. Under Security Settings, select XA Transactions to enable this support.
8. Click OK to save your changes.

**Note:** The installation documentation for JDBC XA connectivity refers to two known problems, see the Microsoft support site for more information:
- KB318818: Performance slows down when you use XA Transactions with SQL Server.

**Parent topic:** Setting up a remote SQL Server database on Windows for a stand-alone production server

**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - **Installing SQL Server**

  The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

  **Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
  - WebSphere Portal 6.1.5 wkplc.properties file reference
  - WebSphere Portal 6.1.5 wkplc_comp.properties file reference
  - WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`

- If you are using a remote database, enter the values for the remote server.

- Use a forward slash (/) instead of a backslash (\).

- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.

- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.

- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - `dbdomain.DbType`
  - `dbdomain.DbName`
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomainDbType, type sqlserver2005.
   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the dbdomainDbUrl property.
   C. For dbdomainDbSchema, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of DbName.
   F. For dbdomainDbUser, type the user ID for the database administrator.
   G. For dbdomainDbPassword, type the password for the database administrator.
   H. For dbdomainDBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.
   I. For dbdomainDBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.
   J. For dbdomainDbHome, type the root location for the database. **Note:**
      - This value is the location to store the database files locally.
      - This path must use two backslashes (\) instead of a forward slash (/).
   K. For dbdomainAdminUrl, type the sqlserver URL without a database attached. This value is used to connect to the server for database administration operations.
   L. For dbdomainDbHostName, type the hostname of the database.
3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domain.DbType`, type of the database you are currently configured to use. The value for `source.domain.DbType` is Derby by default.
B. For `source.domain.DbName`, type the name of the database domain you are currently using.
C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.
D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For `source.domain.DbUrl`, type the url currently used to access your database.
F. For `source.domain.DbUser`, type the name of the user accessing this database.
G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

A. For `sqlserver2005.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.
B. For `sqlserver2005.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
C. For `sqlserver2005.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.
D. For `sqlserver2005.DbConnectionPoolDataSource`, type the name of the implementation class of the connection pool data source.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Setting up a remote SQL Server database on Windows for a stand-alone production server  
**Previous topic:** Installing SQL Server  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

- **Prerequisites**
  - Installing SQL Server
  - Modifying database properties

1. Change to the directory `wp_profile_root\ConfigEngine`
2. To create the databases, type the following command:
   ```
   ConfigEngine.bat create-database -DWasPassword=password
   ```
3. To create the database users, type the following command:
   ```
   ConfigEngine.bat setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:
   ```
   \<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql
   ```

- **Creating users manually**

Use this alternative method for creating users if you have problems running the setup-database task that is documented for setting up a remote SQL Server 2005 database on Windows for a stand-alone production server.

**Parent topic:** Setting up a remote SQL Server database on Windows for a stand-alone production server

**Previous topic:** Modifying database properties

**Next topic:** Windows stand-alone server: Assigning custom filegroups on SQL Server 2005
Creating users manually

Use this alternative method for creating users if you have problems running the setup-database task that is documented for setting up a remote SQL Server 2005 database on Windows for a stand-alone production server.

Before you begin:

- You should have completed installing SQL Server 2005 and creating databases.

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

Create the recommended database users with the SQL Server Management Studio. At least one user is required for each SQL Server 2005 instance.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Connect to your SQL Server 2005 instance.
2. Expand the tree view beneath the SQL Server instance.
3. Expand Security and right-click on Logins.
4. In the opening context menu, select New Login...
5. Enter the database user names.
7. Set a password for the selected user.
8. In the Database Access window, select the database the user must connect to at runtime. The following mappings are recommended: Table 1. List of mappings by database

<table>
<thead>
<tr>
<th>Database</th>
<th>User</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELEASE</td>
<td>RELEASEUSR</td>
</tr>
<tr>
<td>COMMUNITY</td>
<td>COMMUNITYUSR</td>
</tr>
<tr>
<td>CUSTOMIZATION</td>
<td>CUSTOMIZATIONUSR</td>
</tr>
<tr>
<td>WORKFLOW</td>
<td>WORKFLOWUSR</td>
</tr>
<tr>
<td>WMM</td>
<td>WMMDBUSR</td>
</tr>
<tr>
<td>JCRDB</td>
<td>JCR</td>
</tr>
<tr>
<td>FDBKDB</td>
<td>FEEDBACK</td>
</tr>
<tr>
<td>LMDB</td>
<td>LIKEMINDS</td>
</tr>
</tbody>
</table>

9. Click OK to save the user changes.
10. Add the role SqlJDBCXAUser to all the database users that connect to the database using XA connections. This role is available for the database "master" only. To grant users this role:
   A. Open the Microsoft SQL Server Management Studio and connect to the database instance.
   B. Expand Security > Logins underneath the database instance name.
   C. Click the user name to open the Login Properties window.
   D. Select User Mapping.
E. Select database master in the database list.
F. Select SqlJDBCXAUser.
G. Click OK.

Parent topic: Setting up databases
Windows stand-alone server: Assigning custom filegroups on SQL Server 2005

The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin:
- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating filegroups refer to the documentation for the database.

**Prerequisites**
- Installing SQL Server
- Modifying database properties
- Setting up databases

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

1. Determine the names of your custom filegroups.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces that specifies the table space and index space for each property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.indexspace.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword `ON` and a space. For example: `community.COMP_INST.tablespace=ON COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Setting up a remote SQL Server database on Windows for a stand-alone production server  
**Previous topic:** Setting up databases  
**Next topic:** Configuring WebSphere Portal to use SQL Server 2005
Configuring WebSphere Portal to use SQL Server 2005

View information on manually transferring data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**- Prerequisites**

- Installing SQL Server
- Modifying database properties
- Setting up databases

**Tips:**

- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`.
2. Enter the following commands to validate configuration properties.
   ```
   ConfigEngine.bat validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ConfigEngine.bat validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>stopServer.bat server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td>stopServer.bat WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

5. Transfer the database **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

A. Change to the directory `wp_profile_root\ConfigEngine`. 
B. Enter the following command:

```
ConfigEngine.bat database-transfer -DWasPassword=password
```

**Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

```
ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. Change to the directory `wp_profile_root\bin`.

7. Enter the following command to start the WebSphere Portal server:

```
startServer.bat WebSphere_Portal
```

8. Update the SQL Server 2005 statistics for Portal, and JCR databases by opening SQL Server Management Studio, selecting **New Query**, and running the following query:

```
use db_name
exec sp_updatestats @resample='resample';
```

---

**Parent topic:** [Setting up a remote SQL Server database on Windows for a stand-alone production server](#)

**Previous topic:** [Windows stand-alone server: Assigning custom filegroups on SQL Server 2005](#)
Verifying databases

After you configure IBM® WebSphere® Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

You can verify the database connection using IBM WebSphere Application Server or by opening WebSphere Portal in a browser.

- To verify that the WebSphere Portal application server is running by using WebSphere Application Server, complete these steps:

  1. Open the WebSphere Application Server administrative console by entering the following address in a browser:

     http://hostname.example.com:10027/ibm/console

     where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10027 is the default transport port that is created by WebSphere Application Server.

  2. Log into the administrative console.

  3. Depending on your version of WebSphere Application Server, click the appropriate option:

     - For WebSphere Application Server Version 6.1: Click Resources & JDBC Providers.
     - For WebSphere Application Server Version 7.0: Click Resources > JDBC > JDBC Providers

  4. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.

  5. Select the name of the data source that is defined in wkplc_comp.properties. The default data source is wpdbDS.

  6. Select the name of the JDBC provider that is specified in wkplc_dbtype.properties. The default JDBC provider is wpdbJDBC_dbtype, where dbtype is replaced by the value that matches your environment.

  7. Click Test Connection to verify the database connection. If configuration parameters have been changed, you might need to restart WebSphere Application Server for the test to complete.

- To verify that the WebSphere Portal application server is running by opening WebSphere Portal in a browser, enter the following URL in a supported browser:

http://hostname.example.com:10040/wps/portal

where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10040 is the default transport port that is created by WebSphere Application Server.

Parent topic: Setting up a database
Preparing a remote Web server when portal is installed on Windows

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- Prerequisites
  - Setting up a database

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.

2. If using Microsoft Internet Information Server, we recommend updating the *UrlSegmentMaxLength* Registry key to a value of 0 to eliminate potential problems in a WebSphere Portal environment with the default IIS limitation on the length of URL path segments. We also recommend updating the *AllowRestrictedChars* Registry key to a value of 1 to accept hex-escaped characters in request URLs that decode to the U+0000 - U+001F and U+007F - U+009F ranges. Note: Refer to Http.sys registry settings for IIS for information.

3. If using IBM Lotus® Domino®, edit the *NOTES.INI* file on the Web server. Set the *HTTPEnableConnectorHeaders* parameter to 1.

4. If using IBM HTTP Server or Apache Server, edit the *httpd.conf* file on the Web server. Set the *AllowEncodedSlashes* directive to on; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server documentation</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>See the appropriate Apache Server documentation</td>
<td>AllowEncodedSlashes directives</td>
</tr>
</tbody>
</table>

5. Stop the Web server.

6. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. Note: The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

- If using WebDAV: After successfully installing the Web server plug-in, locate and open your *plugin-cfg.xml* file and set *AcceptAllContent* to true.

  Important: Depending on how you use the Web server, you may need to adjust the *ServerIOTimeout* value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your *plugin-cfg.xml* file and set *ServerIOTimeout* to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

7. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.

8. Start the Web server.

Parent topic: Setting up a stand-alone server on Windows
Previous topic: Setting up a database
Next topic: Configuring WebSphere Portal to use a user registry on Windows
Configuring WebSphere Portal to use a user registry on Windows

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- Prerequisites
  - Setting up a database

Perform the following tasks to configure WebSphere Portal to use a user registry:

1. Preparing user registries on Windows
   Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

2. Choosing your user registry model on Windows
   Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

3. Adapting the attribute configuration
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

4. Stand-alone server: Configuring WebSphere Portal to use dynamic groups on Windows
   By default, WebSphere Portal is enabled for static groups. However, the Virtual Member Manager (VMM) allows users to be members of either static or dynamic groups. Static groups are those where a persistent binding exists between a group and its members. Dynamic groups are those where a search query is defined to retrieve the members of a group. If you have your LDAP server configured to use dynamic groups, complete the steps in this task for WebSphere Portal to use dynamic group queries when you setup your LDAP server.

5. Stand-alone server: Enabling referrals for your LDAP user registry on Windows
   Referrals redirect object requests from one LDAP server to another when objects do not exist or cannot be located in a particular directory tree. You should enable referrals if your environment has more than one user registry existing on multiple servers or domains.

Managing your user registry on Windows
Preparing user registries on Windows

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

Choose the appropriate LDAP server to install and setup:

- **Preparing an Active Directory server**
  If you plan to use Active Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing an Active Directory-Lightweight-Directory-Services on Windows**
  If you plan to use an Active Directory-Lightweight-Directory-Services as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Domino Directory server**
  If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a SecureWay Security Server**
  If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Novell eDirectory**
  If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Sun Java System Directory Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Tivoli Directory Server**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

Parent topic: Configuring WebSphere Portal to use a user registry on Windows

Next topic: Choosing your user registry model on Windows
Preparing an Active Directory server

If you plan to use Active Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Active Directory:

1. Perform the following steps to install and configure Active Directory:
   B. Install required Service Packs.
   D. Perform the following steps to install Internet Information Services (IIS), which is required to export server certificates and must be installed before installing Certificate Services:
      1. Open the Control Panel and select Add/Remove Programs.
      2. Choose Add/Remove Windows Components.
      3. Choose the Internet Information Services (IIS) component and then click Next.
   E. Use the following steps to install Certificate Services if you plan on using Active Directory over SSL:
      1. Open the Control Panel and select Add/Remove Programs.
      2. Choose Add/Remove Windows Components.
      3. Select Certificate Services and then click Next.
      4. Select Stand-alone root CA and then click Next. You can also choose other options depends on you needs.
      5. Fill in CA identifying information and then click Next.
      6. Follow the instruction of the Windows Components Wizard. The Windows Server CD is needed.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Create a new user with the Windows administrative tools. Note: There is a 20 character limitation for the user account name.
   B. Set the password for the new user.
   C. Activate the new user with the Windows administrative tools. Set the msDS-UserAccountDisabled attribute to false.

3. Perform the following steps to enable SSL for Active Directory; this step is required to set passwords during sign up and user creation:
   A. Install an Enterprise Certificate Authority on a Windows 2000 Domain Controller, which installs a certificate on a server or install a third-party certificate on the Domain Controller.
   B. Click Start > All Programs > Administrative Tools > Active Directory Users and Computer.
   C. In the Active Directory Users and Computers window, right-click on your domain name and select Properties.
   D. In the Domain Properties dialog box, select the Group Policy tab.
   E. Select the Default Domain Policy group policy and then click Edit.
   F. Select Windows Settings under Computer Configuration.
   G. Select Security Settings and then select Public Key Policies.
   H. Select Automatic Certificate Request Settings.
      1. Use the wizard to add a policy for Domain Controllers. Note: When these requirements are complete, all domain controllers request a certificate and support LDAP over SSL using port 636.
Preparing an Active Directory-Lightweight-Directory-Services on Windows

If you plan to use an Active Directory-Lightweight-Directory-Services as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Active Directory-Lightweight-Directory-Services:

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Create a new user with the Windows administrative tools. **Note:** There is a 20 character limitation for the user account name.
   B. Set the password for the new user.
   C. Activate the new user with the Windows administrative tools. Set the msDS-UserAccountDisabled attribute to false.

**Parent topic:** Preparing user registries on Windows
Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Domino Directory:

1. Perform the following steps to prepare the Domino Directory:
   A. Go to Lotus Domino documentation.
   B. Select the appropriate version tab for your product.
   C. Click the Download/View online link for the Lotus Domino for multiple platforms Information Center.
   D. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > Server installation > Installing Domino on Windows and perform this task.
   E. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > The Domino server setup program and perform this task.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Navigate to the People view of the Domino Directory and then click Add Person.
   B. Enter the following values in the New Person form to create the wpsbind user:
      - Last Name
        - wpsbind
      - User Name
        - wpsbind/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - wpsbind Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsbind
      - Internet password
        - wpsbind
   C. Click Save and Close to save the new person record for wpsbind and return to the People view.
   D. Click Add Person and enter the following values in the New Person form to create the wpsadmin user:
      - Last Name
        - wpsadmin, where wpsadmin in the user ID for the WebSphere Portal Administrator
      - User Name
        - wpsadmin/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - wpsadmin Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsadmin
      - Internet password
        - wpsadmin
   E. Click Save and Close to save the new person record for wpsadmin and return to the People view.
   F. Navigate to the Groups view and click Add Group.
   G. Enter the following values in the New Group form on the Basic tab:
      - Group name
- **wpsadmins**
  
  **Note:** If you plan to configure WebSphere Portal for multiple user registries and your Lotus Domino LDAP will share a realm with another user registry, you must use the hierarchical naming convention for the group names, for example: wpsadmins/DominoDomain, to avoid unexpected results during WebSphere Portal runtime.

- **Group type**
  - Multi-purpose

- **Members**
  - wpsbind/DominoDomain
  - wpsadmin/DominoDomain

  **Note:** You can add additional administrator users if required.

H. Click **Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

3. Perform the following steps to update the access control list for the Domino Directory:

   A. Open the *names.nsf* file in the Lotus Domino Administrator or Lotus Notes client.

   B. Click **File > Application > Access Control** from the main menu to open the access control list for the file.

   C. In the **Access Control List > Basics** panel, ensure that the wpsadmins group has either Author or Editor access.

   D. Add the following Role Types to the wpsadmins group:
      - GroupCreator
      - GroupModifier
      - UserCreator
      - UserModifier

   E. Click **OK**.

**Parent topic:** [Preparing user registries on Windows](#)
Preparing a SecureWay Security Server

If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare SecureWay Security Server:

1. Install SecureWay Security Server; refer to the IBM SecureWay™ Security Server for z/OS® and OS/390® for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   
   **A.** Optional: Perform the following steps to create a new directory suffix:
   
   1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
   2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
   3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
   4. Click **Add**.
   5. Click **OK** to save your changes.
   6. Stop and restart the LDAP server.

   **B.** Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:

   - Use the **PortalUsers.ldif** file as a working example and adapted appropriately to work with your LDAP server.
   - Use the **ContentUsers.ldif** file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   **C.** Replace every `dc=yourco,dc=com` with your suffix.

   **D.** Replace any prefixes and suffixes that are unique to your LDAP server.

   **E.** You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   **F.** Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to **accessGroup**. If using Tivoli Access Manager Version 6, set the **objectclasses** to **groupOfNames**.

   **G.** Save your changes.

   **H.** Follow the instructions provided with your directory server to import the LDIF file.

   **I.** Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on Windows
Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Novell eDirectory:
1. Install Novell eDirectory; refer to eDirectory for information.
2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.
Preparing a Sun Java System Directory Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.
2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on Windows
Preparing a Tivoli Directory Server

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

   
   **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:
   
   A. Optional: Perform the following steps to create a new directory suffix:
      
      1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
      2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4. Click **Add**.
      5. Click **OK** to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      
      - Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.
      - Use the `ContentUsers.ldif` file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every `dc=yourco,dc=com` with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to `accessGroup`. If using Tivoli Access Manager Version 6, set the objectclasses to `groupOfNames`.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on Windows
Choosing your user registry model on Windows

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on Windows**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on Windows**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Next topic: Adapting the attribute configuration
Configuring a stand-alone LDAP user registry on Windows

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on Windows**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on Windows**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on Windows
Configuring a stand-alone LDAP user registry on Windows

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the wp-modify-ldap-security task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the standalone.ldap.realm parameter or you can set ignoreDuplicateIDs=true in the wkplc.properties file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Stand-alone LDAP configuration heading:

   - standalone.ldap.id
   - standalone.ldap.host
   - standalone.ldap.port
   - standalone.ldap.bindDN
   - standalone.ldap.bindPassword
   - standalone.ldap.ldapServerType
   - standalone.ldap.userIdMap
   - standalone.ldap.groupIdMap
   - standalone.ldap.groupMemberIdMap
   - standalone.ldap.userFilter
   - standalone.ldap.groupFilter
   - standalone.ldap.serverId
   - standalone.ldap.serverPassword
   - standalone.ldap.realm
   - standalone.ldap.primaryAdminId
   - standalone.ldap.primaryAdminPassword
   - standalone.ldap.primaryPortalAdminId
   - standalone.ldap.primaryPortalAdminPassword
   - standalone.ldap.primaryPortalAdminGroup
   - standalone.ldap.baseDN
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading:
   - `standalone.ldap.et.group.objectClasses`
   - `standalone.ldap.et.group.objectClassesForCreate`
   - `standalone.ldap.et.group.searchBases`
   - `standalone.ldap.et.personaccount.objectClasses`
   - `standalone.ldap.et.personaccount.objectClassesForCreate`
   - `standalone.ldap.et.personaccount.searchBases`

4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading:
   - `standalone.ldap.gm.groupMemberName`
   - `standalone.ldap.gm.objectClass`
   - `standalone.ldap.gm.scope`
   - `standalone.ldap.gm.dummyMember`

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading:
   - `standalone.ldap.personAccountParent`
   - `standalone.ldap.groupParent`
   - `standalone.ldap.personAccountRdnProperties`
   - `standalone.ldap.groupRdnProperties`

6. Save your changes to the `wkplc.properties` file.

7. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product:
   - `WcmContentAuthorsGroupId`
   - `WcmContentAuthorsGroupCN`

8. Run the `ConfigEngine.bat validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.
   
   **Note:** During the validation task, you may receive the following prompt: *Add signer to the trust store now?*. Press `y` then `Enter`.

9. Run the `ConfigEngine.bat wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to set the stand-alone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents*.

11. Run the `ConfigEngine.bat wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the configure-express task.

A. Edit the `wp_profile_root` PortalServer\wcm\shared\app\config\wcmservices\MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `ConfigEngine.bat action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root\ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

**Parent topic:** Configuring a stand-alone LDAP user registry on Windows

**Related tasks**
- Adapting the attribute configuration
- Using the member fixer tool with IBM Lotus Web Content Management
- Starting and stopping servers, deployment managers, and node agents

### Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

Configuring a stand-alone LDAP user registry over SSL on Windows

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL: **Note:** Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
       1. Log in to the WebSphere Application Server Administrative Console.
       2. Navigate to Security > SSL certificate and key management > SSL configurations.
       3. Click the appropriate SSL configuration from the list. For example,
          - Stand-alone environments: NodeDefaultSSLSettings
          - Clustered environments: CellDefaultSSLSettings

     **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

     4. Click Key stores and certificates.
     5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
     6. Click Signer certificates, click Add, and then enter the following information:
        - Type the Alias the key store uses for the signer certificate.
        - Type the File name where the signer certificate is located.
     7. Click OK and then click Save to save the changes to the master configuration.

   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
      2. Navigate to Security > SSL certificate and key management > SSL configurations.
      3. Click the appropriate SSL configuration from the list. For example,
         - Stand-alone environments: NodeDefaultSSLSettings
Clustered environments: Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

- **Client trust store** **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

  A. See Secure installation for client signer retrieval.

  B. Run the retrieveSigners task from the **wp_profile_root\bin** directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

1. Use a text editor to open the **ssl.client.props** file, located in the **wp_profile_root\properties** directory.

2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter **com.ibm.ssl.trustStore=${CONFIG_ROOT}/cells/wpsbvt/nodes/wpsbvt/trust.p12** to use the default trust store.

3. Save your changes.

2. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root\ConfigEngine\properties** directory.

3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Standalone LDAP configuration heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - **standalone.idap.id**
   - **standalone.idap.host**
   - **standalone.idap.port**
   - **standalone.idap.blndDN**
   - **standalone.idap.bindPassword**
   - **standalone.idap.idapServerType**
   - **standalone.idap.userldMap**
   - **standalone.idap.groupldMap**
   - **standalone.idap.groupMemberldMap**
   - **standalone.idap.userFilter**
   - **standalone.idap.groupFilter**
   - **standalone.idap.serverld**
   - **standalone.idap.serverPassword**
   - **standalone.idap.realm**
   - **standalone.idap.primaryAdminld**
   - **standalone.idap.primaryAdminPassword**
   - **standalone.idap.primaryPortalAdminld**
- standalone.ldap.primaryPortalAdminPassword
- standalone.ldap.primaryPortalAdminGroup
- standalone.ldap.baseDN

4. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.et.group.objectClasses
   - standalone.ldap.et.group.objectClassesForCreate
   - standalone.ldap.et.group.searchBases
   - standalone.ldap.et.personaccount.objectClasses
   - standalone.ldap.et.personaccount.objectClassesForCreate
   - standalone.ldap.et.personaccount.searchBases

5. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attributes heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.gm.groupMemberName
   - standalone.ldap.gm.objectClass
   - standalone.ldap.gm.scope
   - standalone.ldap.gm.dummyMember

6. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the wkplc.properties file under the Default parent, RDN attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.personAccountParent
   - standalone.ldap.groupParent
   - standalone.ldap.personAccountRdnProperties
   - standalone.ldap.groupRdnProperties

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL): **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   Required parameters:
   - standalone.ldap.sslEnabled
   - standalone.ldap.sslConfiguration
   Optional parameters:
   - standalone.ldap.certificateMapMode
   - standalone.ldap.certificateFilter

8. Save your changes to the wkplc.properties file.
9. Run the ConfigEngine.bat validate-standalone-ldap -DWasPassword=password task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, **WasPassword** is the value entered during installation and not a value found in your LDAP user registry. **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.
10. Run the ConfigEngine.bat wp-modify-ldap-security -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to set the stand-alone LDAP user registry.
11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: **Starting and stopping servers, deployment managers, and node agents.**
12. Run the ConfigEngine.bat wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

**Parent topic:** Configuring a stand-alone LDAP user registry on Windows

**Related tasks**
Adapting the attribute configuration
Starting and stopping servers, deployment managers, and node agents
Configuring the default federated repository on Windows

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on Windows**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on Windows**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on Windows**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

**Parent topic:** Choosing your user registry model on Windows
Configuring a federated LDAP user registry on Windows

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Adding an LDAP user registry on Windows**
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=`groupName and the hierarchical format is `cn=`groupName,o=root. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as wpsadmin, this ID cannot exist in the LDAP you are adding.

- **Adding an LDAP user registry over SSL on Windows**
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

**Parent topic:** Configuring the default federated repository on Windows

In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.
2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.id`
   - `federated.ldap.host`
   - `federated.ldap.port`
   - `federated.ldap.bindDN`
   - `federated.ldap.bindPassword`
   - `federated.ldap.ldapServerType`
   - `federated.ldap.baseDN`

3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.et.group.objectClasses`
   - `federated.ldap.et.group.objectClassesForCreate`
   - `federated.ldap.et.group.searchBases`
   - `federated.ldap.et.personaccount.objectClasses`
   - `federated.ldap.et.personaccount.objectClassesForCreate`
   - `federated.ldap.et.personaccount.searchBases`
4. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - federated.ldap.gm.groupMemberName
   - federated.ldap.gm.objectClass
   - federated.ldap.gm.scope
   - federated.ldap.gm.dummyMember

5. Save your changes to the wkplc.properties file.

6. Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. **Note:** See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.
   - WcmContentAuthorsGroupId
   - WcmContentAuthorsGroupCN

7. Run the `ConfigEngine.bat validate-federated-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry.
   **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press `y` then `Enter`.

8. Run the `ConfigEngine.bat wp-create-ldap -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to add an LDAP user registry to the default federated repository. **Note:** Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
    A. Use a text editor to open the wkplc.properties file, located in the `wp_profile_root\ConfigEngine\properties` directory.
    B. Enter a value for the following required parameters in the wkplc.properties file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:
       **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
       - id
       - baseDN
       - nameInRepository
    C. Save your changes to the wkplc.properties file.
    D. Run the `ConfigEngine.bat wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to create a base entry in a repository.
    E. Stop and restart all necessary servers to propagate your changes.

11. Optional: Run the `ConfigEngine.bat wp-query-repository -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to list the names and types of configured repositories.

12. Run the `ConfigEngine.bat wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between
WebSphere Portal and the LDAP server.

13. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the `properties` file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.bat wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.bat wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root\ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `ConfigEngine.bat wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

   A. Edit the `wp_profile_root\PortalServer\wcm\shared\app\config\wcmservices\MemberFixerModule.properties` file.

   B. Add the following lines to the file:

   ```properties
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
   cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
   ```

   Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.
C. Save your changes and close the file.

D. Run the `ConfigEngine.bat action-express-memberfixer -DmemberfixerRealm=realm_name` -
`DPortalAdminPwd=password` -`DWasPassword=password` task, located in the `wp_profile_root\ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. **Value for `realm_name`** when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.idap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

16. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

17. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   **Important:**
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

   **Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

   A. Run the following task from the `wp_profile_root\ConfigEngine` directory: `ConfigEngine.bat wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword` **Important:** You must provide the full distinguished name (DN) for the `newAdminid` parameter.

   B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

   C. Run the following task from the `wp_profile_root\ConfigEngine` directory: `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupid=newadminGroupid` **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

18. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it.

   The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by
duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

**Parent topic:** Configuring a federated LDAP user registry on Windows

Adding an LDAP user registry over SSL on Windows

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: `NodeDefaultSSLSettings`
           - Clustered environments: `CellDefaultSSLSettings`
           **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
        4. Click **Key stores and certificates**.
        5. Click the appropriate trust store from the list; for example, `NodeDefaultTrustStore`.
        6. Click **Signer certificates**, click **Add**, and then enter the following information:
           - Type the **Alias** the key store uses for the signer certificate.
           - Type the **File name** where the signer certificate is located.
        7. Click **OK** and then click **Save** to save the changes to the master configuration.
   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
      2. Navigate to Security > SSL certificate and key management > SSL configurations.
      3. Click the appropriate SSL configuration from the list. For example,
         - Stand-alone environments: `NodeDefaultSSLSettings`
Clustered environments: CellDefaultSSLSettings

Clustered environments: Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

4. Click Key stores and certificates.

5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.

6. Click Signer certificates, click Retrieve from port, and then enter the following information:
   - Type the Host name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL Port used when attempting to retrieve the signer certificate.
   - Type the Alias the key store uses for the signer certificate.

7. Click Retrieve signer information to retrieve the certificate from the port.

8. Click OK and then click Save to save the changes to the master configuration.

- Client trust store Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

A. See Secure installation for client signer retrieval.

B. Run the retrieveSigners task from the wp_profile_root\bin directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

1. Use a text editor to open the ssl.client.props file, located in the wp_profile_root\properties directory.

2. Change the com.ibm.ssl.trustStore parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter com.ibm.ssl.trustStore=${CONFIG_ROOT}/cells/wpsbvt/nodes/wpsbvt/trust.p12 to use the default trust store.

3. Save your changes.

2. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.

3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Federated LDAP Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - federated.ldap.id
   - federated.ldap.host
   - federated.ldap.port
   - federated.ldap.bindDN
   - federated.ldap.bindPassword
   - federated.ldap.ldapServerType
   - federated.ldap.baseDN

4. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - federated.ldap.et.group.objectClasses
   - federated.ldap.et.group.objectClassesForCreate
   - federated.ldap.et.group.searchBases
   - federated.ldap.et.personaccount.objectClasses
   - federated.ldap.et.personaccount.objectClassesForCreate
   - federated.ldap.et.personaccount.searchBases
5. Required: Enter a value for the following required group member parameters in the \texttt{wkplc.properties} file under the Group member attribute heading: \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{federated.idap.gm.groupMemberName}
- \texttt{federated.idap.gm.objectClass}
- \texttt{federated.idap.gm.scope}
- \texttt{federated.idap.gm.dummyMember}

6. Enter a value for the following parameters to enable Secure Socket Layers (SSL): \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

Required parameters:

- \texttt{federated.idap.sslEnabled}
- \texttt{federated.idap.sslConfiguration}

Optional parameters:

- \texttt{federated.idap.certificateMapMode}
- \texttt{federated.idap.certificateFilter}

7. Save your changes to the \texttt{wkplc.properties} file.

8. Optional: Enter the following Web content authors parameters in the \texttt{wkplc_comp.properties} file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. \textbf{Note:} See the \texttt{wkplc_comp.properties} file for specific information about the required parameters and for advanced parameters.

- \texttt{WcmContentAuthorsGroupId}
- \texttt{WcmContentAuthorsGroupCN}

9. Run the \texttt{ConfigEngine.bat validate-federated-ldap -DWasPassword=password} task to validate your LDAP server settings. \textbf{Attention:} If you have not deleted the default file repository, \texttt{WasPassword} is the value entered during installation and not a value found in your LDAP user registry.

\textbf{Note:} During the validation task, you may receive the following prompt: \texttt{Add signer to the trust store now?}. Press \texttt{y} then \texttt{Enter}.

10. Run the \texttt{ConfigEngine.bat wp-create-ldap -DWasPassword=password} task, from the \texttt{wp_profile_root\ConfigEngine} directory, to add an LDAP user registry to the default federated repository. \textbf{Note:} Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: \textit{Starting and stopping servers, deployment managers, and node agents}.

12. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root\ConfigEngine\properties} directory.

B. Enter a value for the following required parameters in the \texttt{wkplc.properties} file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:

\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{id}
- \texttt{baseDN}
- `nameInRepository`
C. Save your changes to the `wkplc.properties` file.
D. Run the `ConfigEngine.bat wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Run the `ConfigEngine.bat wp-query-repository -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to list the names and types of configured repositories.

14. Run the `ConfigEngine.bat wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. Important: When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

15. Perform the following steps to update the user registry where new users and groups are stored:
   - **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.
   - **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:
   - **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `personAccountParent`
   - `groupParent`
   - `personAccountRdnProperties`
   - `groupRdnProperties`
   - The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:
     - `personAccountParent=dc=yourco,dc=com`
     - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

D. Run the `ConfigEngine.bat wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, to delete the old attributes before adding the new attributes.

E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

B. Enter a value for `realmName` or leave blank to update the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `ConfigEngine.bat wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root\ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `ConfigEngine.bat wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

17. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the
Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root`\App\config\wcmservices\MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin, o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors, o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `ConfigEngine.bat` action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password task, located in the `wp_profile_root\ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the wkplc.properties file. If the value for <code>federated.realm</code> is empty, use defaultWIMFileBasedRealm as the default value.</td>
</tr>
</tbody>
</table>

18. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

19. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

**Important:**
- Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
- Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root\ConfigEngine` directory: `ConfigEngine.bat` wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword **Important:** You must provide the full distinguished name (DN) for the `newAdminid` parameter.

B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
C. Run the following task from the *wp_profile_root*\ConfigEngine directory: `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

20. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: Deleting the repository.

Adding a database user registry on Windows

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add. Note: Use the wp_add_DB.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_add_DB.properties helper file.

1. Set up a new database, including creating a new user with appropriate database privileges for accessing the database:

Instructions for setting up databases: Refer to the appropriate documentation for the type of database you want to set up.

Consulting your database administrator: The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

Table 1. Steps for creating a new database to use as a database user registry.

<table>
<thead>
<tr>

<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>Perform the following steps to create a DB2 database: Install DB2. Enter the following database tuning commands: &lt;br&gt; <code>db2 CREATE DB dbname using codeset UTF-8</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING applheapsz 4096</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING stmtheap 32768</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING dbheap 2400</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING locklist 1000</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING logfilsiz 4000</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING logprimary 12</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING logsecond 20</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING logbufsz 32</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING avg_appls 5</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname USING locktimeout 30</code> &lt;br&gt; <code>db2 UPDATE DB CFG FOR dbname using AUTO_MAINT off</code></td>
</tr>
</tbody>
</table>
Perform the following steps to define the **DbDriver** and **DbLibrary** parameter values:

A. Use a text editor to open the `wkplc_dbtype.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

B. Enter a value for the following parameters under the appropriate database type properties heading:
   - `db_type.DbDriver`
   - `db_type.DbLibrary`

C. Save your changes.

**Limitation:** The WebSphere Application Server UserManagement component (VMM) requires access to the following database libraries to use the VMM database functions such as Property Extension and database user registry, however, if the Portal is using the DB2 Type 2 driver, due to functional limitations, VMM must use the DB2 Type 4 driver; see **Configuring a JDBC provider and datasource for federated repositories** for additional information:

<table>
<thead>
<tr>
<th>Database</th>
<th>Oracle</th>
<th>SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 Type 2 driver</td>
<td><code>db2java.zip</code></td>
<td><code>db2jcc.jar;db2jcc_license_cu.jar</code></td>
</tr>
<tr>
<td>DB2 Type 4 driver</td>
<td><code>db2jcc.jar;db2jcc_license_cu.jar</code></td>
<td><code>db2jcc.jar;db2jcc_license_cu.jar;db2jcc_javax.jar</code></td>
</tr>
<tr>
<td>DB2 for z/OS Type 2 driver</td>
<td><code>db2java.zip</code></td>
<td><code>db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar</code></td>
</tr>
<tr>
<td>DB2 for z/OS Type 4 driver</td>
<td><code>db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar</code></td>
<td><code>db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar</code></td>

<td><code>sqlserver.jar;base.jar;util.jar</code></td>
<td></td>
</tr>
</tbody>
</table>
Perform the following steps: add the library paths to the **VMM_JDBC_CLASSPATH** variable:

A. Logon to the WebSphere Application Server Administrative Console.

B. Click **Environment > WebSphere Variables**.

C. Select **scope: cell**.

D. Select the **VMM_JDBC_CLASSPATH** variable or click **New** to create the variable if it does not exist.

E. Enter the complete paths to the library files, separated by ';', in the **Value** field; for example, enter

```plaintext
D:\IBM\SQLLIB\java\db2jcc.jar;D:\IBM\SQLLIB\java\db2jcc_license_cu.jar.
```

Copy the above library files into the **appserver/lib** directory. Then stop and restart the server1 and WebSphere_Portal servers to load the library files. In a clustered environment, you must also stop and restart the Deployment Manager and the nodeagents.

3. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root\ConfigEngine\properties** directory.

4. Enter a value for the following required parameters in the **wkplc.properties** file under the VMM Federated Database Properties heading: **Note**: See the properties file for specific information about the required parameters and for advanced parameters.

```plaintext
- federated.db.DataSourceName
- federated.db.DbType
- federated.db.DbUrl
- federated.db.id
- federated.db.baseDN
- federated.db.DbUser
- federated.db.DbPassword
- federated.db.DbName
```

5. Change the value for the **com.ibm.SOAP.requestTimeout** parameter to 1000.

A. Navigate to the following directory: **wp_profile_root\properties**

B. Locate and open **soap.client.props** with any text editor.

C. Locate the **com.ibm.SOAP.requestTimeout** parameter and change the value to 1000.

D. Save and close **soap.client.props**.

6. Perform the following steps in a clustered environment:

A. Run the **ConfigEngine.bat** **wp-prep-vmm-db-secured-environment -DWasPassword=password -** **DbDomain=federated.db -Db_type.DmgrDbLibrary=local full path of the database jars on the Deployment Manager -DmgrNodeName=dmgr_node_name** task from the **wp_profile_root\ConfigEngine** directory to create the local Deployment Manager WebSphere variable used to access the database jars. **Note**: The **db_type** in **db_type .DmgrDbLibrary** should be set to the type of database you are using, for example **db2**. The **local full path of the database jars on the Deployment Manager** should be one of the following options:

- **DB2 Type 2 driver**: db2java.zip
- **DB2 Type 4 driver**: db2jcc.jar;db2jcc_license_cu.jar
- **DB2 for z/OS Type 2 driver**: db2java.zip
- **DB2 for z/OS Type 4 driver**: db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar
- **Oracle**: ojdbc14.jar
- **SQL Server JDBC driver provided by Microsoft**: sqljdbc.jar
SQL Server JDBC driver provided by DataDirect: sqlserver.jar; base.jar; util.jar

B. Run the following task. Include each node name as a comma separated list in the command:
1. Set the property value for `federated.db.DbType` in `wkplc.properties` if you are using a database user registry.
2. Run the `ConfigEngine.bat wp-node-prep-vmm-db-secured-environment` task from the `wp_profile_root\ConfigEngine` directory on each node to create the variable used to access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

C. Stop and restart all necessary servers to propagate your changes.

7. Run the `ConfigEngine.bat wp-create-db` task from the `wp_profile_root\ConfigEngine` directory, to add a database user registry to the default federated repository. **Note:** Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:
   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.bat wp-set-entitytypes` task, from the `wp_profile_root\ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

10. **Optional:** Run the `ConfigEngine.bat wp-query-repository` task, from the `wp_profile_root\ConfigEngine` directory, to list the names and types of configured repositories.

**Parent topic:** Configuring the default federated repository on Windows

**Parent topic:** Updating your user registry on Windows
Adding realm support on Windows

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - realmName
   - securityUse
   - delimiter
   - addBaseEntry
3. Save your changes to the wkplc.properties file.
4. Run the ConfigEngine.bat wp-create-realm -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to add a new realm to the Virtual Member Manager configuration. **Important:** To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the wkplc.properties file with the base entry information and rerun the wp-create-realm task. Repeat these steps until all realms are created.
5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.
6. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading and then save your changes. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - realmName
   - realm.personAccountParent
   - realm.groupParent
   - realm.orgContainerParent
7. Run the ConfigEngine.bat wp-modify-realm-defaultparents -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to update the default parents per entity type and realm. **Important:** Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types and realms.
8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:
   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
      - realmName
      - addBaseEntry
   C. Save your changes to the wkplc.properties file.
   D. Run the ConfigEngine.bat wp-add-realm-baseentry -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to add an additional LDAP base entries to the realm configuration.
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:
   A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.
   B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.
   C. Create a new group in the Manage Users and Groups portlet to replace the current group.
   D. Run the ConfigEngine.bat wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task, from the wp_profile_root\ConfigEngine directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.
   E. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

11. Optional: Perform the following steps to set the realm you created as the default realm: **Remember:** Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the wp-query-realm-baseentry task to see what base entries are part of the default realm. If the default realm is missing the base entry, run the wp-add-realm-baseentry task to add the base entry to the default realm.
A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
B. For defaultRealmName, type the realmName property value you want to use as the default realm.
C. Save your changes to the wkplc.properties file.
D. Run the ConfigEngine.bat wp-default-realm -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to set this realm as the default realm.
E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:
A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
B. For realmName, type the name of the realm you want to query.
C. Save your changes to the wkplc.properties file.
D. Run the ConfigEngine.bat wp-query-realm-baseentry -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:
A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.
B. Enter a value for realmName or leave blank to update the default realm.
C. Save your changes to the wkplc.properties file.
D. Run the ConfigEngine.bat wp-modify-realm-enable-dn-login -DWasPassword=password task, located in the wp_profile_root\ConfigEngine directory, to enable the distinguished name login. Note: After running this task to enable the full distinguished name login, you can run the ConfigEngine.bat wp-modify-realm-disable-dn-login -DWasPassword=password task to disable the feature.
E. Stop and restart all necessary servers to propagate your changes.

Parent topic: Configuring the default federated repository on Windows
Adapting the attribute configuration on Windows

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. Querying the defined attributes on Windows
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. Adding attributes on Windows
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. Mapping attributes
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. Removing attributes
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Parent topic: Configuring WebSphere Portal to use a user registry on Windows
Previous topic: Choosing your user registry model on Windows
Next topic: Stand-alone server: Configuring WebSphere Portal to use dynamic groups on Windows

Related tasks
Adding an LDAP user registry on Windows
Adding an LDAP user registry over SSL on Windows
Configuring a stand-alone LDAP user registry on Windows
Configuring a stand-alone LDAP user registry over SSL on Windows
Querying the defined attributes on Windows

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `ConfigEngine.bat wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (**PersonAccount**) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on Windows
Adding attributes on Windows

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone environment</td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the wp_profile_root\ConfigEngine directory. Run the ConfigEngine.bat wp-la-install-ear -DWasPassword=password task.</td>
</tr>
<tr>
<td>Clustered environment</td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the wp_profile_root\ConfigEngine directory on the primary node. Run the ConfigEngine.bat wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name task. Where node_name is the name of the node where the deployment manager resides; you can find the node_name value in the WebSphere Application Server Administrative Console under System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: [Starting and stopping servers, deployment managers, and node agents](#).

3. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.

4. Enter a value for the following required parameters in the wkplc.properties file under the VMM Property Extension Properties heading:

   * **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - la.providerURL
   - la.propertyName
   - la.entityTypes
   - la.dataType
   - la.multiValued

5. Save your changes to the wkplc.properties file.

6. Run the ConfigEngine.bat wp-add-property -DWasPassword=password task to add the attribute to the user registry.

   **Note:** This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere.
Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

**Remember:** If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents.*

**Parent topic:** Adapting the attribute configuration  
**Previous topic:** Querying the defined attributes on Windows  
**Next topic:** Mapping attributes

**Related tasks**
Starting and stopping servers, deployment managers, and node agents
Mapping attributes

After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

Perform the following steps to map attributes between WebSphere Portal and your LDAP server; if you have multiple LDAP servers, you will need to perform these steps for each LDAP server:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.

2. Enter a value for one of the following sets of parameters in the wkplc.properties file to identify your LDAP server:
   
   **Note:** Make sure you use the same values you used to configure your LDAP server.

   Table 1. Identifying your LDAP server in the wkplc.properties file.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>The following parameters are found under the LDAP attribute configuration heading. <strong>Note:</strong> See the properties file for specific information about the required parameters and for advanced parameters.</td>
</tr>
<tr>
<td></td>
<td>standalone.ldap.idstandalone.ldap.hoststandalone.ldap.portstandalone.ldap.sslEnabledstandalone.ldap.bindDNstandalone.ldap.bindPasswordstandalone.ldap.baseDN</td>
</tr>
<tr>
<td>Federated</td>

<td>federated.ldap.idfederated.ldap.hostfederated.ldap.portfederated.ldap.sslEnabledfederated.ldap.bindDNfederated.ldap.bindPasswordfederated.ldap.baseDN</td>
</tr>
</tbody>
</table>

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:

   Table 2. Task to check that all defined attributes are available in the configured LDAP user registry.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>ConfigEngine.bat wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory.</td>
</tr>
<tr>
<td>Federated</td>
<td>ConfigEngine.bat wp-validate-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory.</td>
</tr>
</tbody>
</table>

4. Open the ConfigTrace.log file, located in the wp_profile_root\ConfigEngine\log directory, to review the following output for the PersonAccount and Group entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the uid, cn, firstName, sn, preferredLanguage, and ibm-primaryEmail attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory.

6. Enter a value for one of the following sets of parameters in the wkplc.properties file to correct any issues found in the config trace file:

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
</table>
| Stand-alone     | The following parameters are found under the LDAP attribute configuration heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.  
  standalone.ldap.idstandalone.ldap.attributes.nonSupportedstandalone.ldap.attributes.nonSupported.deletestandalone.ldap.attributes.mapping.ldapNamestandalone.ldap.attributes.mapping.p ortalNamestandalone.ldap.attributes.mapping.entityTypes  
  For example, the following values will flag certificate and members as unsupported attributes and will map ibm-primaryEmail to mail and ibm-jobTitle to title for both the PersonAccount and Group entityTypes:  
  standalone.ldap.attributes.nonSupported=certificate, members  
  standalone.ldap.attributes.nonSupported.delete=standalone.ldap.attributes.mapping.ldapName=mail, title  
  standalone.ldap.attributes.mapping.p ortalName=ibm-primaryEmail, ibm-jobTitle  
  standalone.ldap.attributes.mapping.entityTypes=PersonAccount, Group |
7. Save your changes to the wkplc.properties file.

8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>ConfigEngine.bat wp-update-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory</td>
</tr>
<tr>
<td>Federated</td>
<td>ConfigEngine.bat wp-update-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory</td>
</tr>
</tbody>
</table>

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:

A. Enter a value for the following required parameters in the wkplc.properties file:

```
user.attributes.required
user.attributes.nonsupported
```

B. Save your changes to the wkplc.properties file.

C. Run the ConfigEngine.bat wp-update-attribute-config -DWasPassword=password task, from the wp_profile_root\ConfigEngine directory.

D. Stop and restart all necessary servers to propagate your changes.

**Parent topic:** Adapting the attribute configuration
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database: **Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.
   
   A. Open the tool you use to edit your database.
   
   B. Verify that your attribute name is available in the LAPROP table.
   
   C. Delete the required attributes from the LAPROP table.
   
   D. Open the `wimxmlextension.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/model` directory.
   
   E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:
   
   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
   multiValued="true" propertyName="attribute_name">
   <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   
   F. Save your changes to the `wimxmlextension.xml` file.
   
   G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/config` directory.
   
   H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:
   
   ```xml
   <config:propertiesNotSupported name="attribute_name">
   </config:propertiesNotSupported>
   ```
   
   I. Save your changes to the `wimconfig.xml` file.
   
   J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:
   
   A. Open the `wimxmlextension.xml` file.
   
   B. Locate and delete the `propertySchema` definition for the attributes you previously added; for example:
   
   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
   multiValued="true" propertyName="attribute_name">
   <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   
   C. Save your changes to the `wimxmlextension.xml` file.
   
   D. Open the `wimconfig.xml` file.
   
   E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:
   
   ```xml
   <config:attributes name="attribute_name" propertyName="property_name">
   <config:entityTypes>PersonAccount</config:entityTypes>
   </config:attributes>
   ```
   
   F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

**Parent topic:** Adapting the attribute configuration  
**Previous topic:** Mapping attributes
Stand-alone server: Configuring WebSphere Portal to use dynamic groups on Windows

By default, WebSphere Portal is enabled for static groups. However, the Virtual Member Manager (VMM) allows users to be members of either static or dynamic groups. Static groups are those where a persistent binding exists between a group and its members. Dynamic groups are those where a search query is defined to retrieve the members of a group. If you have your LDAP server configured to use dynamic groups, complete the steps in this task for WebSphere Portal to use dynamic group queries when you setup your LDAP server.

Perform the required tasks to configure either a stand-alone or federated LDAP server security.

The steps in this task use groupOfURLs as the object class for dynamic groups and memberURL as the dynamic membership attribute. The actual values for object classes and dynamic membership attributes can vary depending on your LDAP server. For this reason, you should export an LDIF file to verify the object classes and dynamic membership attributes. Either refer to your LDAP documentation or ask your LDAP administrator for instructions on exporting an LDIF file.

Clustered environments: Perform the following steps on the Deployment Manager then synchronize the nodes.

To configure WebSphere Portal to use dynamic groups, do the following:

1. Choose the appropriate set of steps, depending on your LDAP server environment: Table 1. Steps for enabling dynamic groups

<table>
<thead>
<tr>
<th>LDAP server environment</th>
<th>Steps to perform</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone LDAP server or federated LDAP server(s)</td>
<td>Navigate to the following directory: wp_profile_root/cells/cell_name/wim/config. Locate and open wimconfig.xml with any text editor. Add the following line to the <a href="">config:groupConfiguration</a> tag: <code>&lt;config:dynamicMemberAttributes name=&quot;memberurl&quot; objectClass=&quot;groupofurls&quot;/&gt;</code> Save and close wimconfig.xml.</td>
</tr>
<tr>
<td>Federated LDAP server(s)</td>
<td>Log in to the administration console. Select Security &gt; Secure administration, applications, and infrastructure. Under Available realm definitions, select Federated repositories and click Configure. Under Related Items, click Manage repositories. Select the appropriate repository from the list. Under Additional Properties, click Group attribute definition then click Dynamic member attributes. Click New and specify values for the Name and Object class fields as appropriate. For example, Name: memberurl Object class: groupofurls Click OK and save the changes to the master configuration.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.
Stand-alone server: Enabling referrals for your LDAP user registry on Windows

Referrals redirect object requests from one LDAP server to another when objects do not exist or cannot be located in a particular directory tree. You should enable referrals if your environment has more than one user registry existing on multiple servers or domains.

To configure your portal to use LDAP referrals, do the following:

1. Use any text editor to open the `wkplc.properties` file in the following directory: `wp_profile_root/ConfigEngine/properties`.

2. Specify values for the following parameters:
   - `et.ldap.id=ID_of_your_LDAP_server`
   - `et.ldap.host=hostname_of_your_LDAP_server`
   - `et.ldap.referral=follow`

3. Save and close `wkplc.properties`.

4. Run the following task from the `wp_profile_root/ConfigEngine` directory to create an LDAP entity type:
   - UNIX: `./ConfigEngine.sh wp-update-et-ldap -DWasPassword=password`
   - Windows: `ConfigEngine.bat wp-update-et-ldap -DWasPassword=password`
   - IBM® i5/OS: `ConfigEngine.sh wp-update-et-ldap -DWasPassword=password`

5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

Previous topic: Stand-alone server: Configuring WebSphere Portal to use dynamic groups on Windows
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- Prerequisites
  - Setting up a database
  - Base Portal Tuning Scenarios

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services

Parent topic: Setting up a stand-alone server on Windows
Previous topic: Configuring WebSphere Portal to use a user registry on Windows

- IBM WebSphere Portal Performance Troubleshooting Guide
Setting up a cluster

Clusters enable you to scale your WebSphere Portal configuration. Clusters also enable enterprise applications to be highly available because requests are automatically routed to the running servers in the event of a failure. There are numerous cluster configuration, such as horizontal, vertical, multiple, and dynamic.

**Prerequisites**

- Technotes for installation and configuration issues

The following illustration depicts a horizontal cluster configuration where IBM® WebSphere® Portal is installed on multiple servers. This configuration reduces single points of failure, but requires more hardware.

To conserve hardware, you can also set up a vertical cluster with multiple portal instances on a single node.
In response to customer requests, the instructions to setup WebSphere Portal has been improved to provide operating system specific instructions for setting up a production environment. Select your operating system to get started.

After completing the installation remember to tune the servers in your portal environment in order to achieve better performance. The Base Portal Tuning scenarios in the WebSphere Portal and Lotus Web Content Management 6.1.x Performance Tuning Guide provides information about tuning the WebSphere Application Server, WebSphere Portal services, databases, directory servers and more. Base Portal Tuning scenarios are the foundation to most performance tuning. In a cluster environment, there are additional steps you should take to tune WebSphere Application Server, the Web server, and more. First review and take the necessary steps provided in the Base Portal Tuning scenarios, then review and take additional necessary steps in the Tuning a Cluster Environment chapter of the tuning guide. Base Portal Tuning scenarios

Tuning a cluster environment

- **Setting up a cluster on AIX**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Setting up a cluster on HP-UX**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Setting up a cluster on IBM i5/OS**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.
- **Setting up a cluster on Linux**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Setting up a cluster on Solaris**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Setting up a cluster on Windows**
  In a production environment, you can install and configure IBM WebSphere Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

Setting up a cluster on AIX

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company’s needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Prerequisites**
  - [Technotes for installation and configuration issues](#)

Perform the following tasks to set up your production environment on AIX:

1. **Preparing prerequisite and corequisite software on AIX**
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your AIX operating system**
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on AIX**
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Choosing the type of cluster to create on AIX**
   If you installed a IBM WebSphere Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

5. **Preparing a remote Web server when portal is installed on AIX**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Configuring WebSphere Portal to use a user registry on AIX in a clustered environment**
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

7. **Preparing additional nodes on AIX**
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

8. **Tune your servers**
   Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

9. **Configuring search in a cluster on AIX**
   IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.
10. **Setting up multiple clusters on AIX**

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

11. **Sharing database domains between clusters on AIX**

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

**Parent topic:** Setting up a cluster
Preparing prerequisite and corequisite software on AIX

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. **Preparing the WebSphere Application Server Deployment Manager on AIX**
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. **Preparing a remote Web server when portal is installed on AIX**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

Parent topic: Setting up a cluster on AIX
Next topic: Preparing your AIX operating system
Preparing the WebSphere Application Server Deployment Manager on AIX

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command: `cd_root/AIX/architecture/ifpackage/WAS/install`, where `cd_root` is the root directory of the disc and `architecture` is the system’s processor architecture.

2. Choose one of the following options to create a default deployment manager profile:
   **Important:** While creating the default deployment manager profile, enable administrative security. If you use the Profile Management Tool, check the enable administrative security check box. If you use the `manageprofile` command, add the `-enableAdminSecurity=true` parameter to the command line.

3. Run the following command to start the deployment manager: `./startManager.sh`, from the `dmgr_profile_root/bin` directory.

4. Use the following URL to launch the network deployment administrative console: `http://dmgr_hostname:9060/ibm/console`, where `dmgr_hostname` is the fully qualified host name for the WebSphere Application Server Network Deployment.

5. Log into the deployment manager administrative console.

6. Increase the HTTP connection timeouts for the deployment manager.
   A. Click System Administration > Deployment Manager > Web container transport chains.
   B. Increase the timeout values. For the `WCInboundAdmin` and `WCInboundAdminSecure` entries listed in the web container transport chains section, complete the following steps to increase the timeout values:
      1. Click HTTP Inbound Channel.
      2. Change the Read timeout value to 180.
      3. Change the Write timeout value to 180.
      4. Save the configuration changes.

7. Change the timeout request period for the Java Management Extensions (JMX) connector.
   A. Click System administration > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties.
   B. Select the requestTimeout property, and increase the value from 600 to 6000.
   C. Save the configuration changes.

8. Update the maximum Java heap size used by the deployment manager:

---

### Table of Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile Management Tool</td>
<td>See Creating a deployment manager profile for information.</td>
</tr>
<tr>
<td>manageprofile commands</td>
<td>See manageprofile commands for information. Note: If you have a 64-bit environment, only the manageprofiles command is supported when creating profiles.</td>
</tr>
</tbody>
</table>

---

**Operating systems:** AIX, HP-UX, i5/OS, Linux, Solaris, Windows
B. Update the value in the **Maximum Heap Size** field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management Product Documentation page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.

C. Click **OK** and then save your changes.

9. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:

   **Note:** If security is not enabled on your deployment manager, see Enabling security for information before performing this step.

   - For **WebSphere Application Server Version 6.1**: Click **Security > Secure administration, applications and infrastructure** and select **Enable Application Security**. Then save the configuration changes.
   
   - For **WebSphere Application Server Version 7.0**: Click **Security > Global security** and select **Enable Application Security**. Then save the configuration changes.

10. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:

    A. Click **Users and Groups > Manage Users**.
    
    B. Click **Create**.
    
    C. Type the information for the WebSphere Portal administrative users; for example wpsadmin and wpsbind, and then click **Create**.
    
    D. Click **Users and Groups > Manage Groups**.
    
    E. Click **Create**.
    
    F. Type wpsadmins as the name of the WebSphere Portal administrative group and then click **Create**.
    
    G. Click the group you just created; for example wpsadmins.
    
    H. Click the **Members** tab.
    
    I. Click **Add Users**.
    
    J. Search for the users.
    
    K. Select the users you want to add to the group.
    
    L. Click **Add** to add the users to the group.
    
    M. Click **Close** when you are done adding users to the group.
    
    N. Log out of the administrative console.

12. Run the following tasks to stop and restart the deployment manager:

    A. **./stopManager.sh -username admin_userid -password admin_password**, from the dmgr_profile_root\bin directory
    
    B. **./startManager.sh**, from the dmgr_profile_root\bin directory

**Parent topic:** Preparing prerequisite and corequisite software on AIX

**Next topic:** Preparing a remote Web server when portal is installed on AIX
Preparing a remote Web server when portal is installed on AIX

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- Prerequisites
  - Preparing the WebSphere Application Server Deployment Manager on AIX
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the NOTES.INI file on the Web server. Set the HTTPEnableConnectorHeaders parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the httpd.conf file on the Web server. Set the AllowEncodedSlashes directive to on; the directive should be added at the root level as a global directive.

4. Stop the Web server.

5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

   **If using WebDAV:** After successfully installing the Web server plug-in, locate and open your plugin-cfg.xml file and set AcceptAllContent to true.

   **Important:** Depending on how you use the Web server, you may need to adjust the ServerIOTimeout value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your plugin-cfg.xml file and set ServerIOTimeout to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.

7. Start the Web server.

Parent topic: Preparing prerequisite and corequisite software on AIX

Previous topic: Preparing the WebSphere Application Server Deployment Manager on AIX

Parent topic: Setting up a cluster on AIX

Previous topic: Choosing the type of cluster to create on AIX
Preparing your AIX operating system

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on AIX

Perform the following steps to prepare your AIX machine:

1. Set the file descriptor limit to 10240; for example, `ulimit -n 10240`.

2. **Web Content Management only**: Use the `ulimit -f` command to set the maximum size of files that can be created to be at least the size of the largest file you would need to upload to the content server. The command `ulimit -f unlimited` removes any limit on file size.

3. Install and configure X server on AIX (for example, X-Windows or GNOME) to use the graphical user interface the installation program provides. **Note**: X server is not required if installing with a response file or in console mode.

**Parent topic:** Setting up a cluster on AIX

**Previous topic:** Preparing prerequisite and corequisite software on AIX

**Next topic:** Preparing the primary node on AIX
Preparing the primary node on AIX

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

- Prerequisites
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system

Perform the following tasks to prepare your primary node:

1. Installing WebSphere Portal on AIX on the primary node
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. Configure WebSphere Portal to use a remote database
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

3. Configuring the primary node to communicate with the deployment manager on AIX
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. Removing search collections on AIX
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

Parent topic: Setting up a cluster on AIX
Previous topic: Preparing your AIX operating system
Next topic: Choosing the type of cluster to create on AIX
Installing WebSphere Portal on AIX on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method.

Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities
4. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:
   - **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   A. Install the current supported version of WebSphere Application Server as a root user.
   B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:

      1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
      2. Run the following tasks to change the rights of the non-root user:
         ```bash
         chmod -R g+rwx /usr/IBM
         chgrp -R group_name/IBM
         chmod -R g+wr /tmp
         ```
C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

 Advance Installation parameters: To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

 Restriction: When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

 Table 1. Installation task options

<table>

</tr>
<tr>
<td>Console mode</td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td>Silent install</td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. Important: Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

 Note: If the installation program does not detect a WebSphere Application Server instance that you know exists, exit the installation program and pass the WebSphere Application Server instance location using the command line; for example, ./install.sh -W was.undetectedWas="/my/WAS/location".

 Note: If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

6. Verify your installation was successful; access WebSphere Portal using the http://yourserver:yourport/wps/portal format. Run the ./ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the ./ConfigEngine.sh configure-express -DPortalAdminPwd=password -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

 Restriction: Run the configure-express task before configuring your database, user registry, context root, security, etc. If you ran any tasks other than the install task, do not run this task.

 Note: See http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html for tutorials on how to use the sample content.

 The sample content includes:

 - Creates a group called contentAuthors; members of this group are given privileges to create content in the sample
Internet and intranet sites. Navigate to the **Administration** area and then click **Access > Users and Groups**.

- Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0".

Navigate to the **Administration** area and then click **Portal Content > Web Content Libraries**.

- Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the **Environment** area.

- Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to **Theme Customizer** and then select the style.

- Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.

- Creates two virtual portals with context roots of **wps/portal/intranet** and **wps/portal/internet**. These are the sample Internet and intranet sites. Go to **http://yourserver:yourport/wps/portal/internet** and **http://yourserver:yourport/wps/portal/intranet** to access them.

- Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the **Administration** area and then click **Access > Credential Vault > Manage System Vault Slots**.

- Modifies the portlet palette to include some new portlets. Click the **Portlets** link to see the portlet palette.

Optional: If you ran the **configure-express** task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as *uid=xyzadmin,o=defaultWIMFileBasedRealm*. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:

A. Edit the `wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

B. Add the following line to the file:

   ```
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
   ```

   Replace `portal_admin_DN` with the distinguished name of the portal administrator.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory.

9. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

   **Note:** The starting port parameter is required for a successful completion of the **modify-ports-by-startport** task.

   Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the **modify-ports-by-startport** task.

   A. Stop the server1 and WebSphere_Portal servers.

   B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

SIB_MQ_ENDPOINT_SECURE_ADDRESS=10028  
ORB_LISTENER_ADDRESS=10034
```
Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

Password considerations when transferring data manually

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts.

Alternatively, you can specify the password on the command line using the following syntax:

- Windows: `ConfigEngine.bat task_name -Dpassword_property_key=password_value`
- UNIX: `.ConfigEngine.sh task_name -Dpassword_property_key=password_value`
- i5/OS: `ConfigEngine.sh task_name -Dpassword_property_key=password_value`

As with other properties, each password property must have the -D prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each -D property=value setting.

- Prerequisites

  - Installing WebSphere Portal on AIX on the primary node
  - Technotes for database connectivity issues

- Configuring WebSphere Portal to use DB2

View information on installing and setting up DB2 to work with WebSphere Portal.

- Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle RAC

View information on installing and setting up Oracle RAC to work with WebSphere Portal.

- Configuring WebSphere Portal to use SQL Server

View information on installing and setting up SQL Server to work with WebSphere Portal.

- Verifying databases

After you configure IBM WebSphere Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

3. Creating remote databases
   A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

4. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

5. Modifying database properties
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

6. Optional: Configuring JCR collation support
   View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

7. Configure WebSphere Portal to use DB2
   View information on how to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

8. Configuring DB2 for large file handling in Web Content Management
   If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

9. Optional: Changing driver types
   WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2

View information on installing DB2 for use with WebSphere Portal.

Before you begin:

- Make sure DB2 is set up with updated kernel parameters according to the recommendations in the DB2 Quick Beginnings guide at DB2 Technical Support.

- **(For Type 2 drivers only):** DB2 Connect must be installed on the same system as WebSphere Portal, and have the same name as the server profile name.

- When you install DB2 using the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.

1. If you are using the JDBC driver in type 2 mode, configure your DB2 Connect client with the following commands. If you are using a remote database, complete this step separately from the WebSphere Portal installation.

   - db2 update dbm cfg using tp_mon_name WAS
   - db2 update dbm cfg using spm_name hostname, where hostname is the host name of WebSphere Portal.

     Because the default for spm_name is the hostname itself, specifying the hostname parameter is optional. If your hostname is more than eight characters, use empty double quotes (" "). For example, db2 update dbm cfg using spm_name " ".

2. Before installing DB2, log in with a user ID that has administrative authority.

3. To install DB2, follow the instructions that are provided with the DB2 documentation to install DB2 and the required fix pack.

Create users

View the steps to set up users for DB2 to work with WebSphere Portal.
Before you begin: You should have completed Installing DB2.

- Prerequisites
  - Installing DB2

For all databases, use one user with administrative rights on the operating system and the DB2 installation. This user can be the database administrative user that is created automatically by the DB2 installation program. This user is the database configuration user that will be used for configuration tasks: creating database tables and performing database transfer. If you choose to have WebSphere Portal also create the databases, the database user should be given SYSADM rights. You only need to manually create an administrator ID when you do not want to use an existing DB2 administrator ID.

A common user name is `db2inst1`, but you can assign any user name as long as it has administrative access and follows the limitations listed here. Do not change the user name after creating it.

The limitations on user names are:

- User names can contain one to eight characters.
- Group and instance names can contain one to eight characters.
- Names cannot be any of the following: `users`, `admins`, `guests`, `public`, `local`
- Names cannot begin with: `IBM`, `SQL`, `SYS`
- Names cannot include accented characters.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Following are the basic steps to create new users and grant privileges. For more information, refer to the DB2 product documentation.

1. From the DB2 Control Center, expand the object tree until you find the DB Users folder.
2. Right-click the DB Users folder and select `Create/Add`. The Create DB User notebook opens.
3. In the User name field, type a user ID.
4. Assign an authority for the user.
5. Click `OK`.

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Installing DB2
Next topic: Creating remote databases
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before creating these databases, note the following information:

- Use IBM® DB2 Universal Database™ Enterprise Server Edition JDBC driver, JCC, type 4.

- If the DB2 JDBC type 4 driver is used, only the instructions on the remote server are required. You do not need to install the DB2 client software, and you do not need to complete the steps related to the DB2 client.

- The client software, DB2 Connect, must be correctly configured to connect to the remote DB2 server instance, for example, `db2inst1`.

- These instructions assume that a remote DB2 server and DB2 Connect are already installed and running. For information on installing DB2 Connect, see the DB2 product documentation.

- **Prerequisites**
  - Installing DB2
  - Create users

To create a database, you must be a DB2 System Administrator with sufficient database privileges (SYSADM or at a minimum SYSCtrl).

1. Log in to the DB2 server system as a user with sufficient database privileges.
2. Initialize a DB2 command environment by opening a command prompt and typing `su - db2inst1`, where `db2inst1` is the database user. The prompt changes to your operating system shell prompt, for example: `$`. In this mode, you must type `db2` at the beginning of each command and use double quotation marks (""") around the entire command. The following example shows how to use the double quotes; it is not an actual command that you run:

   ```sql
   db2 "CREATE REGULAR TABLESPACE SMS PAGESIZE 4 K MANAGED BY SYSTEM USING ('sms') BUFFERPOOL SMSPOOL"
   ```

   **Note:** If you are using the Command Line Processor (CLP), refer to your DB2 documentation for details. The command prompt is `db2=>`. In this mode, commands can be entered without the `db2` prefix or the double quotation marks. However, the following steps assume you are not using the CLP and are entering commands from your operating system shell prompt, for example: `$`.

3. Run the following commands on the DB2 server system to configure the DB2 database instance:

   **Environment** | **Description**
   --- | ---
   **DB2** | `db2set DB2_RA_TO_RS=YES`
   | `db2set DB2_EVALUNCOMMITTED=YES`
   | `db2set DB2_INLIST_TO_NLJN=YES`
   | `db2 "UPDATE DBM CFG USING query_heap_sz 32768"`
   | `db2 "UPDATE DBM CFG USING maxagents 500"`
   | `db2 "UPDATE DBM CFG USING sheapthres 0"`

4. **(Important)** Failure to complete this step will result in an unsuccessful database transfer. Run the following commands on the DB2 server system to create the necessary databases.

   **Notes:**
   - Replace `dbname` with the actual name of the database. Run the commands and each time replace `dbname` with the actual values for release, community, customization, Java Content Repository, Feedback, and Likeminds. You will need to run the commands once for each database for a total of six times. **Remember:** DB2 database names cannot
A. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (\texttt{jcrdb}).

- \texttt{jcrdb} is the name of the database used to store user data and objects

- \texttt{jcr} is the jcr user for \texttt{jcrdb} \textbf{Note:} This value can be replaced with any ID that has administrative authority.

- \texttt{dbpassword} is the password for the jcr user for the \texttt{jcrdb}

\机能\texttt{db2 "CONNECT TO jcrdb USER jcr USING dbpassword"}
\机能\texttt{db2 "CREATE BUFFERPOOL ICMLSFREQBP4 SIZE 1000 PAGESIZE 4 K"}
\机能\texttt{db2 "CREATE BUFFERPOOL ICMLSVOLATILEBP4 SIZE 16000 PAGESIZE 4 K"}
\机能\texttt{db2 "CREATE BUFFERPOOL ICMLSMAINBP32 SIZE 16000 PAGESIZE 32 K"}
\机能\texttt{db2 "CREATE BUFFERPOOL CMBMAIN4 SIZE 1000 PAGESIZE 4 K"}
\机能\texttt{db2 "CREATE REGULAR TABLESPACE ICMLFQ32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLFQ32') BUFFERPOOL ICMLSMAINBP32"}
\机能\texttt{db2 "CREATE REGULAR TABLESPACE ICMLNF32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLNF32') BUFFERPOOL ICMLSMAINBP32"}
\机能\texttt{db2 "CREATE REGULAR TABLESPACE ICMVFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMVFQ04') BUFFERPOOL ICMLSVOLATILEBP4"}
\机能\texttt{db2 "CREATE REGULAR TABLESPACE ICMSFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMSFQ04') BUFFERPOOL ICMLSFREQBP4"}
\机能\texttt{db2 "CREATE REGULAR TABLESPACE CMBINV04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('CMBINV04') BUFFERPOOL CMBMAIN4"}
\机能\texttt{db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('icmlssystspace32') BUFFERPOOL ICMLSMAINBP32"}
\机能\texttt{db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE4 PAGESIZE 4 K MANAGED BY SYSTEM USING ('icmlssystspace4') BUFFERPOOL ICMLSVOLATILEBP4"}
\机能\texttt{db2 "DISCONNECT jcrdb"}
\机能\texttt{db2 "TERMINATE"}

B. For JDBC Type 2 connections only: On DB2 Connect, use a text editor to open the \texttt{/etc/services} file. If it does not specify the DB2 connection service port, add the following text to specify the port for the remote DB2 instance:

\机能\texttt{db2c_\_db2inst1port1/tcp # DB2 connection service port}

where \texttt{db2inst1} is the name of the DB2 instance ID on the system, and \texttt{port1} with the actual port number that is
assigned to the DB2 connection service in your DB2 server installation. The connection service port on the DB2
Client system, WebSphere Portal server, must match the connection service port on the DB2 server. The ports
should match by number but not necessarily by name.

C. Set up the correct service name by entering the following command on the DB2 server system:
   `db2 "UPDATE DBM CFG USING svcename svce_name"` where `svce_name` is the connection service port name that is specified above.

D. For JDBC Type 2 connections only: On DB2 Connect, set DB2COMM to TCP/IP by using the db2set command
   `db2set DB2COMM=tcpip`.

E. For JDBC Type 2 connections only: Catalog the TCP/IP node with the IP address of the remote database server on
   DB2 Connect:
   `db2 "catalog tcpip node remote_db_node_alias remote database_server_node server connection_service_port"` where:
   - `remote_db_node_alias` is the alias name of the database server that you are defining for the WebSphere Application
     Server node name. The alias name can contain one to eight characters.
   - `database_server_node` is the fully qualified host name of your database server system.
   - `connection_service_port` is the name of the DB2 connection service port that is configured in the `/etc/services`
     file on the database server system.

F. For JDBC Type 2 connections only, catalog the WebSphere Portal databases on DB2 Connect, where:
   - `remote_db_name_domain`, is the cataloged name of the databases on the server system for each domain.
   - `domain_alias_name`, is the database alias names that you are defining.
   - `remote_db_node_alias` is the name that was used previously when you cataloged the TCP/IP node in the previous
     step.
   The alias for each database must be different from the actual database name and can only contain up to eight
characters:
   `db2 "catalog db remote_db_name_release as release_alias_name at node remote_db_node_alias"
   db2 "catalog db remote_db_name_community as comm_alias_name at node remote_db_node_alias"
   db2 "catalog db remote_db_name_customization as cust_alias_name at node remote_db_node_alias"
   db2 "catalog db remote_db_name_fdbkdb as fdbkdb_alias_name at node remote_db_node_alias"
   db2 "catalog db remote_db_name_lmdb as lmdb_alias_name at node remote_db_node_alias"
   db2 "catalog db remote_db_name_jcrdb as jcrdb_alias_name at node remote_db_node_alias"

G. For JDBC Type 2 connections only: Log out of DB2 Connect by entering `db2 "terminate"`.

H. For JDBC Type 2 connections only, on DB2 Connect, test your remote connection by issuing the following command
   in the DB2 command window: `db2 "connect to alias_name user username using password"`, where `alias_name`
   is the alias name that you defined above, `username` is the database user, and `password` is the password assigned to
   the database user.

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Create users
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword **IN** and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`

   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - **Windows**: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - **UNIX**: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Creating remote databases  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`
- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
- dbdomain.DbType
- dbdomain.DbName
- dbdomain.DbUrl
- dbdomain.DbSchema

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomain.DbType, type db2.
   B. For dbdomain.DbName, type the name of the WebSphere Portal domain database. Notes:
      - This value is also the database element in the dbdomain.DbUrl property.
      - This value is the TCP-IP alias for the database.
   C. For dbdomain.DbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For dbdomain.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomain.DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should match the value of DbName.
   F. For dbdomain.DbUser, type the user ID for the database administrator.
   G. For dbdomain.DbPassword, type the password for the database administrator.
   H. Optional: For dbdomain.DbRuntimeUser, type the user ID of the database user that should be used by WebSphere Portal to connect to the database at runtime.
   I. If dbdomain.DbRuntimeUser is specified, you must set dbdomain.DbRuntimePassword to be the password of the runtime database user.
   J. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.
K. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

L. For `dbdomain.XDbName`, type the database loop back alias that needs to be set if you plan to use the `create-database` task. **Note:** Required only for local databases using a JDBC Type 2 driver.

M. For `dbdomain.DbNode`, type the value for the node database. Set this value if you want to call `create-database`. **Note:** Required only for local databases.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

B. For `source.domainName`, type the name of the database domain you are currently using.

C. For `source.domainSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domainDbUrl`, type the url currently used to access your database.

F. For `source.domainDbUser`, type the name of the user accessing this database.

G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `db2.DbDriver`, type the name of the JDBC driver class.

   B. For `db2.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `db2.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Assigning custom table spaces  
**Next topic:** Configuring JCR collation support
Configuring JCR collation support

View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

1. Stop the WebSphere Portal server:
   . ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password

2. If using a remote DB2 server, copy the following files from the WebSphere Portal server to a temporary directory on the remote DB2 server:
   PortalServer_root/jcr/prereq.jcr/config/collation.jar
   PortalServer_root/jcr/prereq.jcr/config/registerCollationUDFTemplate.sql

3. Set up collation on the database where the JCR domain is located.
   A. Change to the directory db2_instance_owner_home/sqlib/function.
   B. Execute the command: Remote DB2:
db2 -tvf temporary location/collation.jar icm/CollationUDF.class
   Local DB2:
db2 -tvf PortalServer_root/jcr/prereq.jcr/config/collation.jar icm/CollationUDF.class
   C. If using a local DB2, change to the directory wp_profile_root/PortalServer/jcr/config.
   D. Open the file registerCollationUDFTemplate.sql and change all SCHEMA references to the JCR schema; for example, JCR. The value set for SCHEMA should match the value set for the jcr.DbSchema property. You specify jcr.DbSchema in the configuration file wkplc_comp.properties when you modify database properties.
   E. Connect to the JCR database by running db2 connect to <jcrdb> user <userid> using <password>.
   F. Execute the script by running the command Remote DB2:
db2 -tvf temporary location/registerCollationUDFTemplate.sql
   Local DB2:
db2 -tvf wp_profile_root/PortalServer/jcr/config/registerCollationUDFTemplate.sql
   G. Disconnect from the JCR database.
   H. Restart the DB2 instance.

4. Verify that the UDF is registered properly.
   A. Log in as the db2instanceID. Open a DB2 terminal window, and type db2. From the command line, type the command:
      connect to JCRDB user userid using password. You must connect to the JCR database using the userid and password of the WebSphere Portal JCR data source.
   B. Execute the following command in the previous substep. If the command completes successfully, the UDF is registered correctly as follows:
      values schema.sortkeyj('abc','en'), where schema is the schema used in the previous substep.

5. Edit the icm.properties file, located in wp_profile_root/PortalServer/jcr/lib/com/ibm/icm directory. Add the following section to the end of the file:
   # Enable/Disable collation support for all DB2 platforms
6. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Modifying database properties
Next topic: Configure WebSphere Portal to use DB2
Configure WebSphere Portal to use DB2

View information on how to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

**Tips:**
- To run these tasks as a non-root user, you must first run the task chown -R *non-root_user* *WebSphereDir*.
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

**Steps for transferring data to another supported database**

1. If you are running a type 2 connection, before transferring data edit the `db2cli.ini` file. Failure to follow these steps will cause the database transfer to hang at the task `action-process-constraints`.
   A. Locate the file `/home/db2inst1/sqlib/cfg/db2cli.ini`.
   B. Add the following to the end of the file. Leave an empty line after `ReturnAliases=0.[COMMON]`
   ```
   DYNAMIC=1
   ReturnAliases=0
   ```

2. Perform this step only if you are installing multiple instances of WebSphere Portal. Change the maximum number of databases `MAX_NETBIOS_CONNECTIONS` to increase the default configured number of databases. For example, enter the following command at the database prompt: `set client MAX_NETBIOS_CONNECTIONS 254` A message indicates success if the number was increased.

3. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.

4. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2. 
   ```
   /home/db2inst1/sqlib/db2profile
   ```
   where `db2inst1` represents your database instance**Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

5. Enter the following commands to validate configuration properties. 
   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```
./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password

6. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.

7. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

8. Transfer the database:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory wp_profile_root/ConfigEngine.

   B. Enter the following command: ./ConfigEngine.sh database-transfer -DWasPassword=password

      **Note:**
      - To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
      - If you have been storing data in IBM® Derby for a long time, database transfer could fail with OutOfMemory exceptions. If database transfer fails, add the following property to the command in this step: ./ConfigEngine.sh database-transfer -DDbtJavaMaxMemory=1536M -DWasPassword=password

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files and then repeat this step.

9. After transferring the database tables, perform a reorg check to improve performance. Perform this step for each database alias in the property file.

   A. Connect to a database with the following command:

   ```
   db2 connect to database_alias user db2admin_userid using password
   ```

   **Note:** Additional options might be required if additional security has been installed. Refer to DB2 Universal Database commands by example for links to the command reference.

   B. After it is connected, run the following commands from the DB2 prompt:

   ```
   db2 reorgchk update statistics on table all > xyz.out
   ```

   C. Look in the reorg column for entries marked with a * (star or asterisk) in the file xyz.out. For each line with a *, note the `tablename` and run the following command for each `tablename`:

   ```
   db2 reorg table tablename db2 terminate db2rbind
database_name -l db2rbind.out -u db2_admin -p password
   ```

   D. The output file db2rbind.out is only created when there is an error for the `db2rbind` command.

10. Change to the directory wp_profile_root/bin.

11. Enter the following command to start the WebSphere Portal server:

    ```
    ./startServer.sh WebSphere_Portal
    ```

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Configuring JCR collation support

**Next topic:** Configuring DB2 for large file handling in Web Content Management

**Related information**

- [#SQL0443N with SYSIBM:CLI:-805 when invoking a CLI catalog function after upgrading to DB2 UDB Version 8.1 FixPak](#SQL0443N with SYSIBM:CLI:-805 when invoking a CLI catalog function after upgrading to DB2 UDB Version 8.1 FixPak)
Configuring DB2 for large file handling in Web Content Management

If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configure WebSphere Portal to use DB2

  **Note:** You only need to perform these steps if you are using Web Content Management.

1. Log into the WebSphere Application Server administrative console.
2. Click **Resources > JDBC > Data sources**.
3. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
4. Select the name of the data source that is defined in `wkplc_comp.properties` for the JCR database domain. The default data source is `wpdbDS`.
5. Click **Custom properties**.
6. Ensure that the `fullyMaterializeLobData` property is set to `false`. 

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Configure WebSphere Portal to use DB2

**Next topic:** Changing driver types
Changing driver types

WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Before you begin, ensure that the following conditions are met:
- The WebSphere Portal database has been successfully transferred to DB2 using the database-transfer configuration task.
- The files wkplc_comp.properties and wkplc_dbtype.properties have been modified to set the correct values for the DB2 drivers that you are switching to:

  In the file wkplc_comp.properties set each `<Domain>.DbUrl` property using the following formats:
  
  # db2 (type 2):       { jdbc:db2:wpsdb }
  # db2 (type 4):       { jdbc:db2://<YourDatabaseServer>:50000/wpsdb:returnAlias=0; }

  In the file wkplc_dbtype.properties set the `db2.DbLibrary` property using the following format:
  
  # For DB2 Type 2 driver use `<SQLLIB>/java/db2java.zip`
  # For DB2 Type 4 driver use `<SQLLIB>/java/db2jcc.jar:<SQLLIB>/java/db2jcc_license_cu.jar`

  In the file wkplc_dbtype.properties set the `db2.DbDriver` property using the following format:
  
  # For DB2 Type 2 driver use COM.ibm.db2.jdbc.app.DB2Driver
  # For DB2 Type 4 driver use com.ibm.db2.jcc.DB2Driver

**Note:** If WebSphere Portal is installed on the same machine as the DB2 server and you switch from a JDBC Type 4 connection to a JDBC Type 2 connection, verify that you have created the alias names for the DB2 databases as described in Creating remote databases and that the alias names are specified for the databases in the file wkplc_comp.properties. When switching from a JDBC Type 2 connection to a JDBC Type 4 connection, remove the database alias names and refer to the databases directly. This is required because of a limitation in the DB2 Universal JDBC driver.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties
- Configure WebSphere Portal to use DB2
- Configuring DB2 for large file handling in Web Content Management

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`. 
2. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2. 

   ```bash
   /home/db2inst1/sqllib/db2profile
   ```

   where `db2inst1` represents your database instance

   **Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

3. Enter the following commands to validate configuration properties:

   ```bash
   DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```
4. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>.stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>.stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

6. Change to the directory `wp_profile_root/ConfigEngine`.

7. To change from one supported driver to the other, run the following task to connect the database, including only the domains that require the switch. `.ConfigEngine.sh connect-database -Drelease.DbPassword=password -Dcustomization.DbPassword=password -Dcommunity.DbPassword=password -Djcr.DbPassword=password -Dfeedback.DbPassword=password -Dlikeminds.DbPassword=password -DWasPassword=password`

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server: `.startServer.sh WebSphere_Portal`

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Configuring DB2 for large file handling in Web Content Management
Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

1. Installing DB2 for z/OS
   View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

2. Creating users
   Complete this procedure to set up users for IBM DB2 Universal Database™ for z/OS® to work with IBM WebSphere Portal.

3. Creating remote databases
   A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

4. Optional: Creating the Java Content Repository database
   View information on setting up your Java Content Repository database to work with WebSphere Portal.

5. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

6. Configuring WebSphere Portal to use DB2 for z/OS
   View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2 for z/OS

View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

The following prerequisites must exist separately from the WebSphere Portal installation:

- If you are using the DB2 Legacy Type 2 JDBC driver, configure your DB2 Connect client with the following commands:
  - `db2 update dbm cfg using tp_mon_name WAS`
  - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name for the machine where the DB2 Connect client is installed (same as portal machine).

- If you are using the DB2 Legacy Type 2 JDBC driver, enable extended shared memory usage with the following commands:
  - `export EXTSHM=ON`
  - `db2set DB2ENVLIST=EXTSHM`
  - `db2start`

  To make the change permanent, you must add the environment variable by adding the following to the `profile.env` file:
  ```
  DB2ENVLIST='EXTSHM'
  in /home/db2inst/sqllib/userprofile add: export EXTSHM=ON
  ```

  **Note:** The shell must be reopened before restarting DB2 for z/OS.

- Both type 2 and type 4 drivers are supported. If you are using the DB2 Legacy Type 2 JDBC driver, the DB2 Connect client must be installed on the same machine as WebSphere Portal to connect to the remote database.

- The DB2 subsystem must be on a supported z/OS platform.

- Update the BP8K0 catalog bufferpool to 35,000 buffers before performing database transfer. You should change this value based on your environment. The SYSIBM.SYSDATABASE table resides in this bufferpool and is used extensively by DB2 for z/OS during database transfer.

To use DB2 for z/OS as the database software for WebSphere Portal, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions. Refer to the Planning for DB2 for z/OS topic for additional considerations for configuring DB2 for z/OS as the WebSphere Portal database.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Next topic:** Creating users
Creating users

Complete this procedure to set up users for IBM® DB2 Universal Database™ for z/OS® to work with IBM WebSphere® Portal.

Before you begin: You should have completed Installing DB2 for z/OS.

- **Prerequisites**
  - Installing DB2 for z/OS

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

- If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, you must create a unique database user for each WebSphere Portal instance. By default all database table names include the name of the database user used to access the data. Therefore, to prevent table name conflicts, you must create a unique database user for each WebSphere Portal instance on the shared DB2 for z/OS subsystem.

- Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Use the following steps to grant access permissions to the database users. Repeat these steps for each WebSphere Portal instance you are setting up.

1. Create all database user IDs in the security product you are using on z/OS. For `jcrschema`, the database schema name for IBM Java Content Repository data, create a group and connect it to the database user ID for Java Content Repository data, `jcr`. The following sample shows the RACF definition of such a user ID and group, where `jcr` is the database user ID for Java Content Repository data, `yourDefaultUserGroup` is your default RACF group for database user IDs, `jcrschema` is the database schema name for Java Content Repository data, and `yourDefaultGroup` is your default RACF group for groups. If you have some other security product such as Top Secret or ACF2 instead of RACF, translate the sample RACF definition into the appropriate syntax before running the job.

   ```
   ADDUSER jcr DFLTGRP(yourDefaultUserGroup) NAME('WAS DB2 ACCESS USER')
   PW USER(jcr) NOINTERVAL
   ALU jcr PASSWORD(*******) NOEXPIRED
   ADDGROUP jcrschema SUPGROUP(yourDefaultGroup)
   CONNECT jcr GROUP(jcrschema)
   ```

2. Run the following SQL statements using a tool like SPUFI while logged on to the DB2 subsystem to grant appropriate rights on the newly created databases. If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, be sure to use the database user associated with the database user ID for Java Content Repository data, `jcr`. The following SQL statements show the rights to be granted for each set of database user IDs.

   ```
   (C) create/alter tablespaces
   (C) create/alter tables
   (C) create/alter indice;
   (C+R) read/write data
   (C) - at configuration time
   (R) - at runtime
   ```

where:
- `releasenameonzos`, `communitynameonzos`, `customizationnameonzos`, and `releaseusr`, `communityusr`, `customizationusr` represent the databases and database users, respectively, of the WebSphere Portal instance you are setting up. (These users must be created on the host system.)
- `jcrdbnameonzos` and `jcr` are the database and database user, respectively, for Content Repository data.
- `fdbkdbnameonzos` and `feedback` are the database and database user, respectively, for Feedback data.
- `lmddbnameonzos` and `lmdbusr` are the database and database user, respectively, for Likeminds data.
- `jcrschema` is the database schema name for Content Repository data.

3. Grant the necessary access rights to all users who might require them. Depending on the architecture that you choose, these users might include Java Content Repository and Feedback users.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS  
**Previous topic:** Installing DB2 for z/OS  
**Next topic:** Creating remote databases
Creating remote databases

A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

Before you begin, complete the following prerequisites:

- These instructions assume that you will use a local IBM® DB2 Universal Database™ Enterprise Server Edition Connect to connect to a remote IBM DB2 Universal Database for z/OS® server, and that IBM WebSphere® Application Server, WebSphere Portal, and DB2 Connect will be installed on the same machine.
- To run SQL statements, you can use a tool like SPUFI. The specified statements include CREATE STOGROUP, CREATE DATABASE and CREATE TABLESPACE. For CREATE STOGROUP you have to replace the icmvolumes and icmvcat variables with volume serial numbers and a catalog name for your environment. For CREATE TABLESPACE you can specify a specific BUFFERPOOL. Refer to the DB2 for z/OS SQL Reference for a description of these options.
- Ensure that a TEMP database is created for your subsystem. You can use the following statements to create a TEMP database:

```
CREATE DATABASE db_name AS TEMP;
CREATE TABLESPACE ts_name IN db_name;
```

- Log on to the DB2 subsystem on the host server. DB2 system administrator rights are needed to create the databases.
- Replace variables as follows:
  - releasenameonzos, communitynameonzos, and customizationnameonzos are the WebSphere Portal databases for WebSphere Portal and Member Manager data.
  - fdbkdbnameonzos and fdbkbts are the database and table space, respectively, for Feedback data.
  - lmdbnameonzos and lmdbts are the database and table space, respectively, for LikeMinds data.
- Because large objects are stored in columns that can become very large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for table spaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see Technote 1306637, Managing LOB logging in DB2 for z/OS.

**Prerequisites**

- Installing DB2 for z/OS
- Creating users

Use the following steps to set up WebSphere Portal with a remote instance of DB2 for z/OS. Refer to Planning for DB2 for z/OS for a list of databases and table space names. If you are configuring multiple WebSphere Portal instances to use a single DB2 subsystem, be sure to use the database and table space names associated with the WebSphere Portal instance you are setting up.

1. `CREATE DATABASE releasenameonzos CCSID UNICODE;`
2. `CREATE DATABASE communitynameonzos CCSID UNICODE;`
3. `CREATE DATABASE customizationnameonzos CCSID UNICODE;`
4. Execute the steps in the topic Creating the Java Content Repository database.
5. `CREATE DATABASE fdbkdbnameonzos CCSID UNICODE;`
6. `CREATE TABLESPACE fdbkdbts IN fdbkdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500 LOCKSIZE ROW;`
7. `CREATE DATABASE lmdbnameonzos CCSID UNICODE;`
8. CREATE TABLESPACE lmdbts IN lmdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500;

- Managing LOB logging in DB2 for z/OS
Creating the Java Content Repository database

View information on setting up your Java Content Repository database to work with WebSphere Portal.

First, you need to create multiple databases for scalability.

The IBM Java Content Repository database grows in size as the IBM® WebSphere® Portal server is used. To support this growth, which includes the dynamic creation of many new tables within the database, the WebSphere Portal server allows you to create multiple databases within a single IBM DB2 Universal Database™ for z/OS® subsystem. A minimum of two databases is recommended, but more can be created if necessary. A single database setup is not recommended; it will quickly become constrained. See the Performance guides on the product documentation Web site for more information.

Each database that is created must begin with a common prefix; there is no convention required for the remainder of the name. For example, to create \( \times x \) number of databases, you may choose to use the following commands:

```sql
CREATE DATABASE JCRDB01
CREATE DATABASE JCRDB02
...
CREATE DATABASE JCRDBXX
```

In this case, \( JCR \) is the common prefix. You also have to select a maximum number of user-defined tables (UDT) that each database will be allowed to hold; the recommended value is 400.

**- Prerequisites**

- Installing DB2 for z/OS
- Creating users
- Creating remote databases

A sample script of the commands that you can use to create the Java Content Repository database in your DB2 for z/OS installation is shown below. The sample demonstrates the creation of a single database. To follow the recommendation of creating at least two databases, duplicate the commands for each additional database as indicated below. Find a template of these commands in the file `PortalServer_root installer/wp.config/config/templates/db/db2_zos/jcr_sample.sql`.

**Notes:**

- It is not necessary to duplicate every tablespace definition in every database.
- In order to run the commands shown in the sample, you must know the database name and the IDs of the MVS volumes where the Java Content Repository database tables will be stored.
- Edit the template file for your installation environment before running the commands shown in the sample:
  - Replace `jcrdbnameX` with the name of the database. Remember that each database name must begin with a common prefix.
  - Replace `stogroup` with the name of your storage group.
  - Replace `icmvolumes` with the IDs of the MVS volumes where the Java Content Repository database tables will be stored. These values are assigned by the database administrator.
  - Replace `icmcatalog` with the name of the virtual catalog.
  - Replace `jcr` with the name of database user ID.
  - Replace `4kbp` with the name of your 4K bufferpool.
  - Replace `32kbp` with the name of your 32K bufferpool.
  - Replace `jcrschema` with the schema name of your Java Content Repository domain.
--DROP DATABASE jcrdbnameX
--DROP STOGROUP stogroup
--DROP ALIAS jcrschema.ICMFICTITIOUS

CREATE STOGROUP stogroup VOLUMES (icmvolumes) VCAT icmvcat
GRANT USE OF STOGROUP stogroup to jcr

CREATE DATABASE jcrdbnameX STOGROUP stogroup BUFFERPOOL 4kbp INDEXBP 4kbp CCSID UNICODE

Note: The following two tablespace commands must be created in every database:
CREATE TABLESPACE ICMLFQ32 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 32kbp CCSID UNICODE
CREATE TABLESPACE ICMTSQ04 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 500 SECQTY 200 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 4kbp CCSID UNICODE

Note: The following tablespaces are required in the first database only:
CREATE TABLESPACE ICMLFQ32 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 32kbp CCSID UNICODE
CREATE TABLESPACE ICMTSQ04 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 5000 SECQTY 200 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 4kbp CCSID UNICODE

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Creating remote databases
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root` /PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.
- When using IBM® DB2 Universal Database™ for z/OS® as a data store, WebSphere Portal requires that its indexes are not padded. Therefore, you must set the DSNZPARM parameters to `RETVLCFK=NO` or `PADIX=NO`, or both.

- **Prerequisites**
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.

2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each `.tablespace` entry in the mapping file. Assignments to `.indexspace` entries are ignored.

   The table space name must be qualified by the database name and prepended by the keyword `IN` and a space. For example:`community.COMP_INST.tablespace=IN COMM8KSPACE`

   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - **Windows:** ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Creating the Java Content Repository database
Next topic: Configuring WebSphere Portal to use DB2 for z/OS
Configuring WebSphere Portal to use DB2 for z/OS

View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.
   A. Locate the file /home/db2inst1/sqllib/cfg/db2cli.ini.
   B. Add the following to the end of the file. Leave an empty line after ReturnAliases=0.[COMMON]

   DYNAMIC=1
   ReturnAliases=0

2. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.

3. Enter the following commands to validate configuration properties...
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password

4. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

6. Transfer the database: Note: Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory wp_profile_root/ConfigEngine.
   B. Enter the following command:.

   ./.ConfigEngine.sh database-transfer -DWasPassword=password

   Note: To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter
the following command: 

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files and then repeat this step.

7. From the command line processor, reset the check pending status on the WebSphere Portal table spaces listed here.

CHECK DATA is a DB2 batch utility that is invoked through JCL or through the DB2 utility panels. Type the following utility commands to check pending status:

```
check data tablespace releasenameonzos.TS320A
check data tablespace releasenameonzos.TS280A
check data tablespace releasenameonzos.TS300A
check data tablespace releasenameonzos.TS2110A
check data tablespace releasenameonzos.TS830A
check data tablespace communitynameonzos.TS8000B
check data tablespace communitynameonzos.TS8011B
check data tablespace communitynameonzos.TS280B
check data tablespace customizationnameonzos.TS2110C
check data tablespace jcrdbnameonzos.ICMSFQ04
check data tablespace jcrdbnameonzos.TS2111D
```

where releasenameonzos, communitynameonzos, and customizationnameonzos are the names of your WebSphere Portal databases, and jcrdbnameonzos is the name of your JCR database. Refer to the Utility Guide and Reference for DB2 for z/OS for additional details.

8. Run the RUNSTATS utility as shown in the following example:

```
LISTDEF JCRDBZOS INCLUDE TABLESPACE JCRDBZOS.* BASE
RUNSTATS TABLESPACE LIST JCRDBZOS INDEX(ALL) KEYCARD TABLE(ALL)
LISTDEF JCRDB01 INCLUDE TABLESPACE JCRDB01.* BASE
RUNSTATS TABLESPACE LIST JCRDB01 INDEX(ALL) KEYCARD TABLE(ALL)
...```

9. Start the WebSphere Application Server.

10. Verify that the WebSphere Portal application server is running by opening the following URL in a browser:

```
http://hostname.companyname.com:port_number/wps/portal
```

where hostname.companyname.com is the fully qualified host name of the machine where WebSphere Portal is running and port_number is the transport port that is created by WebSphere Application Server.

If you have performed database transfer in a clustered environment, you must explicitly copy the wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties file from the primary node on which the database-transfer task was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values specified in the icm.properties file.

1. Stop the portal server on the secondary node.
2. Copy the wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties file from the primary node and replace the icm.properties file on the secondary node with the new file from the primary node.
3. Start the portal server on the secondary node.

Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

1. Installing Oracle
   View information on how to install Oracle for use with WebSphere Portal.

2. Creating users
   View the steps to set up users for Oracle to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle databases to work with WebSphere Portal.

4. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configure WebSphere Portal to use Oracle
   This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing Oracle

View information on how to install Oracle for use with WebSphere Portal.

You can use Oracle as the database software. You must install Oracle separately and before performing a database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle
Next topic: Creating users
Creating users

View the steps to set up users for Oracle to work with WebSphere Portal.

Before you begin:

- You should have installed Oracle.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Start the Oracle SQL command line processor ‘SQL*Plus’ by entering `sqlplus /nolog` on the operating system command prompt.

2. Log in to the Oracle database by executing command `connect user/password@database name`. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

3. Create the WebSphere Portal user `dbname.DbUser`, where `dbname` is replaced by release, community, or customization.

   A. Log in to the database in which you want to create the new users.

   B. Create the users that you need in the appropriate databases by entering the following commands in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects. All names must be in lower case.

   ```sql
   SQL> create user releaseusr identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO releaseusr;
   SQL> create user communityusr identified by password
   default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO communityusr;
   SQL> create user customizationusr identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO customizationusr;
   SQL> create user jcr identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO jcr
   ```

4. Connect to the Feedback database:

   A. Enter the following command: `SQL> connect`.

   B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database. For example, `system/manager@fdbkdb` will log the administrative user system with a password of manager into the fdbkdb database.
C. Create the Feedback user:

```
SQL> create user feedback identified by password
           default tablespace user_tablespace
           temporary tablespace temp_tablespace;
```

GRANT UNLIMITED TABLESPACE TO feedback

D. Log out of the command line tool using the command SQL> exit.

5. Connect to the LikeMinds database:

A. Enter the following command:

```
SQL> connect
```

B. Enter 

```
user-name: username/password@dbname, where username is an existing administrative user in the database.
```

For example, system/manager@lmdb will log the administrative user system with a password of manager into the

lmdb database.

C. Create the LikeMinds user:

```
SQL> create user lmdbusr identified by password
           default tablespace user_tablespace
           temporary tablespace temp_tablespace;
```

GRANT UNLIMITED TABLESPACE TO lmdbusr

D. Log out of the command line tool using the command SQL> exit.

6. Perform the following steps to verify that you can connect to the database with the user ID and password that you just created:

A. Enter the SQL> connect command to connect to the content database.

B. Enter 

```
user-name: username/password@dbname, where username is an existing administrative user in the database.
```

For example, system/manager@jcrdb will log the administrative user system with a password of manager into the Oracle
database.
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal. For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:

  - **db_block_size** = 8192 bytes
  - **db_cache_size** = 307,200 bytes
  - **db_files** = 1024 files
  - **log_buffer** = 65536 bytes
  - **open_cursors** = 1500 cursors
  - **pga_aggregate_target** = 204,800 bytes
  - **pre_page_sga** = true
  - **processes** = 300 processes
  - **shared_pool_size** = 204,800 bytes

**Note:** If you are using IBM Java Content Repository, the open_cursors value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the parallel_max_servers to 1200.
- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:

  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.

  - **EXACT**
- When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

- **Prerequisites**
  - Creating users

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Creating users

**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:

- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and Like Minds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:

  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.

- Depending on which database domain has to be configured, replace `dbdomain` with:

  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:

  - `ddomain.DbType`
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.

   A. For dbdomainDbType, type oracle.

   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the dbdomainDbUrl property.

   C. For dbdomainDbSchema, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomainDbName should be the same value used for the dbdomainDbSchema.

      **Restriction:** The value for dbdomainDbSchema must equal the value for dbdomainDbUser.

   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback

   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:**
      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. **When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.**

   F. For dbdomainDbUser, type the user ID for the database administrator. **Restriction:** The value for dbdomainDbUser must equal the value for dbdomainDbSchema.
For **dbdomain**.DbPassword, type the password for the database administrator.

For **dbdomain**.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.

For **dbdomain**.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.

For **dbdomain**.DbHome, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For **source.domain**.DbType, type of the database you are currently configured to use. The value for **source.domain**.DbType is Derby by default.

B. For **source.domain**.DbName, type the name of the database domain you are currently using.

C. For **source.domain**.DbSchema, type current schema identifier for objects within the database for this domain.

D. For **source.domain**.DataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For **source.domain**.DbUrl, type the url currently used to access your database.

F. For **source.domain**.DbUser, type the name of the user accessing this database.

G. For **source.domain**.DbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_dbtype.properties.

A. For oracle.DriverManager, type the name of the class that SqlProcessor uses to import SQL files.

B. For oracle.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For oracle.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

- **Prerequisites**
  - Creating users
  - Creating databases
  - Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`

3. To create the database users, type the following command:

   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `\<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**

Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- Prerequisites
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.

2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:

   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb./data/ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '&dbpath./&jcrdb./data/ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb./data/ICMVFQ04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb./data/ICMSFQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '&dbpath./&jcrdb./index/ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   ```

   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.

   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.

   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

Parent topic: Configuring WebSphere Portal to use Oracle
Previous topic: Setting up databases
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

- Prerequisites
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configure WebSphere Portal to use Oracle
Configure WebSphere Portal to use Oracle

This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

Tips:
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.
2. Enter the following commands to validate configuration properties.

   ```bash
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>
5. Transfer the database. **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

A. Change to the directory `wp_profile_root/ConfigEngine`.

B. Enter the following command: `./ConfigEngine.sh database-transfer -DWasPassword=password`  
   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: `./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password`  

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example: `SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);`

7. Change to the directory `wp_profile_root/bin`.

8. Enter the following command to start the WebSphere Portal server: `./startServer.sh WebSphere_Portal`

---

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:

- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon (GSD), oracle listeners, and agents.

  $ gsdctl start
  $ lsnrctl start
  $ agentctl start

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Next topic:** Create users
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:

- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**

- Installing Oracle RAC

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects: Tip: Balance the storage of user objects among tablespaces to prevent running out of space with overuse of `user_tablespace`. Also consider increasing the size of `user_tablespace` when handling a high volume of users.

   ```sql
   SQL> create user username identified by password
       default tablespace user_tablespace
       temporary tablespace temp_tablespace;
   ```

2. Log in by entering the command `$ sqlplus` in SQL*Plus:

3. Enter the command `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

4. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults.

   ```sql
   SQL> create user releaseusr identified by password;
   SQL> create user communityusr identified by password;
   SQL> create user customizationusr identified by password;
   SQL> create user jcr identified by password;
   ```

5. Connect to the content database by entering the command `SQL> connect`.

6. Enter the following, where `username` is an existing administrative user in the database. `user-name: username/password@dbname` For example, `system/manager@jcrdb` will log the administrative user system with a password of manager into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the `jcr` user, grant all necessary privileges. If you do not grant privileges, you will receive the error `ICMADMIN lacks CREATE SESSION Privilege logon denied`. 

 Portal, Version 6.1.5
 Operating systems: AIX, HP-UX, i5/OS, Linux, Solaris, Windows

1180
when you try to connect with the `jcr` user:

```
SQL> create user jcr identified by password default tablespace users temporary tablespace temp;
```

8. Connect to the Feedback database:
   A. Enter the following command: `SQL> connect` 
   B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database. For example, `system/manager@fdbkdb` will log the administrative user system with a password of manager into the `fdbkdb` database.

9. Create the Feedback user:

```
SQL> create user feedback identified by password default tablespace users temporary tablespace temp;
```

10. Connect to the LikeMinds database:
```
SQL> connect
```

11. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@lmdb` will log the administrative user system with a password of manager into the `lmdb` database.

12. Create the LikeMinds user:
```
SQL> create user lmdbusr identified by password default tablespace users temporary tablespace temp;
```

13. Log out of the command line tool using the command `SQL> exit`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Installing Oracle RAC  
**Next topic:** Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal.

For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:

  - `db_block_size = 8192` bytes
  - `db_cache_size = 307,200` bytes
  - `db_files = 1024` files
  - `log_buffer = 65536` bytes
  - `open_cursors = 1500` cursors
  - `pga_aggregate_target = 204,800` bytes
  - `pre_page_sga = true`
  - `processes = 300` processes
  - `shared_pool_size = 204,800` bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the `parallel_max_servers` to 1200.

- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:

  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.

  - **EXACT**
- When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Create users

**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:

  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
- `dbdomainDbType`
- `dbdomainDbName`
- `dbdomainDbUrl`
- `dbdomainDbSchema`

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   A. For `dbdomainDbType`, type `oracle`.
   B. For `dbdomainDbName`, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the `dbdomainDbUrl` property.
   C. For `dbdomainDbSchema`, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The `dbdomainDbName` should be the same value used for the `dbdomainDbSchema`.

   **Restriction**: The value for `dbdomainDbSchema` must equal the value for `dbdomainDbUser`.

   D. For `dbdomainDataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - `releaseDS`
      - `communityDS`
      - `customizationDS`
      - `jcrDS`
      - `lmdbDS`
      - `feedback`

   E. For `dbdomainDbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note:
      - The database element of this value should match the value of `DbName`.

      For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
For dbdomain.DbUser, type the user ID for the database administrator. **Restriction:** The value for dbdomain .DbUser must equal the value for dbdomain.DbSchema.

G. For dbdomain.DbPassword, type the password for the database administrator.

H. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.

I. For dbdomain.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.

J. For dbdomain.DbHome, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For source.domainDbType, type the database you are currently configured to use. The value for source.domainDbType is Derby by default.

B. For source.domainDbName, type the name of the database domain you are currently using.

C. For source.domainDbSchema, type current schema identifier for objects within the database for this domain.

D. For source.domainDataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For source.domainDbUrl, type the url currently used to access your database.

F. For source.domainDbUser, type the name of the user accessing this database.

G. For source.domainDbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_dbtype.properties.

A. For oracleDbType, type the name of the class that SqlProcessor uses to import SQL files.

B. For oracleDbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For oracleJdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`

3. To create the database users, type the following command:

   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   ```sql
   '<WP_root>/base/wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql'.
   ```

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**

Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.

2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb.data/ICMLFQ32_01.dbf' size 300M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   
   create tablespace ICMLNF32 datafile '&dbpath./&jcrdb.data/ICMLNF32_01.dbf' size 25M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   
   create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb.data/ICMVFQ04_01.dbf' size 25M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   
   create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb.data/ICMSFQ04_01.dbf' size 150M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   
   create tablespace ICMLSNDX datafile '&dbpath./&jcrdb.index/ICMLSNDX_01.dbf' size 10M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   
   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Setting up databases  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tables/pages/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tables/pages/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - `release`
   - `community`
   - `customization`
   - `jcr`
   - `feedback`
   - `likeminds`

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `TABLESPACE` and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`

   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
- UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Creating JCR table spaces
Next topic: Configuring WebSphere Portal to use Oracle RAC
Configuring WebSphere Portal to use Oracle RAC

This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

Tips:
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:
  ```
  jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))
  (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME))
  ```
- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

Steps for transferring data to another supported database
1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties:

   ```sh
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWsPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWsPassword=password
   ```

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

   ```
   Option                           Description
   WebSphere Application Server     ./stopServer.sh server1 -username admin_userid -password admin_password
   WebSphere Portal                 ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```

5. Transfer the database: Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory `wp_profile_root/ConfigEngine`.
   B. Enter the following command:

   ```sh
   ./ConfigEngine.sh database-transfer -DWsPassword=password
   ```

   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

   ```sh
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWsPassword=password
   ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

   ```sql
   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
   ```

7. Specify the JDBC URL to connect to the cluster:
   A. Login to the WebSphere Application Server Administrator Console
   B. Navigate to Resources > JDBC Providers
   C. If there is a value in the Node field, remove it and click Apply.
   D. For each Oracle JDBC provider, repeat the following steps:
      1. Click the provider name.
      2. Select Data Sources.
      3. Click the name of the data source.
      4. Under the Oracle data source properties, modify the URL attribute according to Oracle RAC configuration:

         ```
         jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))(ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME)))
         ```

      5. Save your changes.

8. Change to the directory `wp_profile_root/bin`.
9. Enter the following command to start the WebSphere Portal server:

   ```sh
   ./startServer.sh WebSphere_Portal
   ```

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Assigning custom table spaces
Configuring WebSphere Portal to use SQL Server

View information on installing and setting up SQL Server to work with WebSphere Portal.

1. Installing SQL Server
   View the steps to install SQL Server for use with WebSphere Portal.

2. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

3. Optional: Assigning custom filegroups
   The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

4. Configuring WebSphere Portal to use SQL Server 2005
   This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing SQL Server

View the steps to install SQL Server for use with WebSphere Portal.

Before you begin this task, complete the following prerequisites:

- You should have completed reviewing the Planning for SQL Server topic.
- You must install SQL Server separately from WebSphere Portal.
- WebSphere Portal requires either the DataDirect Connect for JDBC 3.7 JDBC driver or the Microsoft SQL Server JDBC Driver.
- You can obtain the DataDirect Driver from DataDirect Technologies. The JDBC driver consists of two parts: the JDBC driver libraries and JTA libraries. The JDBC driver libraries must be put on the WebSphere Portal system, while the JTA libraries are intended for SQL Server.
- You can obtain the Microsoft SQL Server JDBC Driver from Microsoft. See the Microsoft SQL Server product documentation for installation details.

The following section provides instructions for installing SQL Server for use with IBM® WebSphere® Application Server and WebSphere Portal. These steps are the same for both the DataDirect and Microsoft drivers unless noted.

1. Install SQL Server and all required patches.
2. Select the authentication mode for this installation:
   - Windows Authentication Mode
   - Mixed Mode (Windows Authentication and SQL Server Authentication)
     Either authentication mode allows the user who is specified as the database administrator in the wkplc_comp.properties file to log in to the SQL server. Mixed Mode authentication allows either a Windows user or a SQL server user, or both, to log in to the SQL Server.
3. In the SQL Server Setup panel, **Components to Install**, select the following components, which are required services for WebSphere Portal:
   - **SQL Server Database Services**
     - **Integration Services** The option Integration Services, creates the directory DTS/Binn, where you will need to copy files when you install Microsoft SQL Server JDBC drivers and enable XA connections.
4. Complete the installation using SQL Server documentation as a guide.
5. Enable TCP/IP connectivity in the **SQL Server Configuration Manager**.
6. Install the JDBC driver using one of these methods:
   - Installing DataDirect Connect for JDBC drivers on UNIX
   - Installing DataDirect Connect for JDBC drivers on Windows
   - Installing Microsoft SQL Server JDBC drivers and enabling XA connections
7. Network the connections for MSDTC in the Windows Component Services as described in Microsoft Help and Support.
8. Start SQL Server.

**Installing DataDirect Connect for JDBC drivers on UNIX**
1. Purchase and download DataDirect Connect for JDBC and save file 360connectjdbc.jar in a temporary work directory.
2. To create the required files, run the following command from the directory that contains 360connectjdbc.jar:

`jar -xvf 360connectjdbc.jar`

3. Run `/Installer.sh` in the same directory.

4. When installation is complete, change directory to `/installation/lib`, where `installation` is the directory in which you installed the DataDirect Connect for JDBC drivers.

5. Run the following command to change the permissions on the JAR files in the `installation/lib` directory:

`chmod 777 *.jar`

6. Change the ownership and group of these files by running the following commands in the `installation/lib` directory:

```bash
chgrp system_grp *.jar
chown root *.jar
```

Where `system_grp` is the system group as labeled by your operating system.

**Installing Microsoft SQL Server JDBC drivers and enabling XA connections**

1. Download and install the Microsoft SQL Server JDBC driver.

2. Copy file `sqljdbc_xa.dll` from the `xa` subdirectory to the `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll` directory of the SQL Server installation.

3. Start the database server.

4. Ensure that the Distributed Transaction Coordinator has been started. The status can be verified in the list of services in the Computer Management console.

5. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.

6. Select **File > Open > File** and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.

7. Execute the script by selecting **Query > Execute**. **Note:** Any warnings that appear in the messages section of the application window that say that stored procedures cannot be found can be safely ignored.

   A. Open the Windows Registry Editor (regedit) and navigate to the element `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XADLL`

   B. From the menu bar, select **Edit > New > String Value** to create a new parameter named `sqljdbc_xa.dll` in that element.

   C. Change the value of the new parameter to the location of the `sqljdbc_xa.dll` file copied in Step 2 above, for example: `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll`

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

**Prerequisites**
- Installing SQL Server

1. Change to the directory `wp_profile_root/ConfigEngine`
2. To create the databases, type the following command:
   ```bash
   ./ConfigEngine.sh create-database -DWasPassword=password
   ```
3. To create the database users, type the following command:
   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal: `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use SQL Server  
**Previous topic:** Installing SQL Server  
**Next topic:** Assigning custom filegroups

**Related tasks**
Create users and databases for SQL Server 2005 on AIX and UNIX
Assigning custom filegroups

The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin:
- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablesomes/dbdomain.space_mapping.properties file.
- For details on creating filegroups refer to the documentation for the database.

- **Prerequisites**
  - Installing SQL Server
  - Setting up databases

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

1. Determine the names of your custom filegroups.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablesomes that specifies the table space and index space for each property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.indexspace.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword `ON` and a space. For example: `community.COMP_INST.tablespace=ON COMM8KSPACE`

   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - **Windows**: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
   - **UNIX**: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
   - **i5/OS**: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use SQL Server
Previous topic: Setting up databases
Next topic: Configuring WebSphere Portal to use SQL Server 2005
Configuring WebSphere Portal to use SQL Server 2005

This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005.

As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**Prerequisites**

- Installing SQL Server
- Setting up databases

**Tips:**

- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties.
   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

5. Transfer the database:

   **Note:** Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.
   B. Enter the following command:

   ```
   ./ConfigEngine.sh database-transfer -DWasPassword=password
   ```

   **Note:** To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to
include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: `./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password`

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. Change to the directory `wp_profile_root/bin`.
7. Enter the following command to start the WebSphere Portal server: `./startServer.sh WebSphere_Portal`
8. Update the SQL Server 2005 statistics for Portal, and JCR databases by opening SQL Server Management Studio, selecting **New Query**, and running the following query: `use db_name exec sp_updatestats @resample='resample';`

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Assigning custom filegroups
Verifying databases

After you configure IBM® WebSphere® Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

- **Prerequisites**
  - [Technotes for database connectivity issues](#)

You can verify the database connection using IBM WebSphere Application Server or by opening WebSphere Portal in a browser.

- To verify that the WebSphere Portal application server is running by using WebSphere Application Server, complete these steps:
  1. Open the WebSphere Application Server administrative console by entering the following address in a browser:
     
     ```
     http://hostname.example.com:10027/ibm/console
     ```
     where `hostname.example.com` is the fully qualified host name of the machine where WebSphere Portal is running and 10027 is the default transport port that is created by WebSphere Application Server.
  2. Log into the administrative console.
  3. Depending on your version of WebSphere Application Server, click the appropriate option:
    - For **WebSphere Application Server Version 6.1**: Click **Resources & JDBC Providers**.
    - For **WebSphere Application Server Version 7.0**: Click **Resources > JDBC > JDBC Providers**
  4. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
  5. Select the name of the data source that is defined in wkplc_comp.properties. The default data source is `wpdbDS`.
  6. Select the name of the JDBC provider that is specified in wkplc_dbtype.properties. The default JDBC provider is `wpdbJDBC_dbtype`, where `dbtype` is replaced by the value that matches your environment.
  7. Click **Test Connection** to verify the database connection. If configuration parameters have been changed, you might need to restart WebSphere Application Server for the test to complete.

- To verify that the WebSphere Portal application server is running by opening WebSphere Portal in a browser, enter the following URL in a supported browser:
  ```
  http://hostname.example.com:10040/wps/portal
  ```
  where `hostname.example.com` is the fully qualified host name of the machine where WebSphere Portal is running and 10040 is the default transport port that is created by WebSphere Application Server.

**Parent topic:** Configure WebSphere Portal to use a remote database
Configuring the primary node to communicate with the deployment manager on AIX

After installing IBM® WebSphere® Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

- Prerequisites
  - Installing WebSphere Portal on AIX on the primary node
  - Configure WebSphere Portal to use a remote database

Perform the following steps to configure WebSphere Portal to communicate with the deployment manager:

1. Run the `./ConfigEngine.sh collect-files-for-dmgr -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory of the primary node, to create an archive or compressed file containing all the files which need to be copied to the Deployment Manager. **Note:** The archive or compressed file will be placed in the `wp_profile_root/filesForDmgr` directory and the file will be called `filesForDmgr.zip`.

2. Stop the deployment manager.

3. Expand the `filesForDmgr.zip` file into the installation root directory of the Deployment Manager; for example in the `/opt/IBM/WebSphere/AppServer` directory. **Note:** If the Deployment Manager profile was not created in the default `AppServer/profiles/Dmgr01` directory, then the `metadata_wkplc.xml` file, located in the `AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml` directory in the zip file, must be placed into the correct Deployment Manager profile directory.

4. If the Deployment Manager profile is running on the same application server where WebSphere Portal is installed, remove the `com.ibm.ws.portletcontainer.deploytask_6.1.5.jar` file from the `AppServer/plugins` directory.

5. Start the deployment manager.

**Parent topic:** Preparing the primary node on AIX  
**Previous topic:** Configure WebSphere Portal to use a remote database  
**Next topic:** Removing search collections on AIX

**Related tasks**

- Configuring Portal Search in a cluster on AIX
Removing search collections on AIX

If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

- **Prerequisites**
  - Installing WebSphere Portal on AIX on the primary node
  - Configure WebSphere Portal to use a remote database
  - Configuring the primary node to communicate with the deployment manager on AIX

Perform the following steps to delete all existing search collections from the primary node:

1. Log on to WebSphere Portal.
2. Navigate to Administration > Search Administration > Manage Search and then click Search Collections.
3. Click the Delete Collection icon for each search collection and then click OK until they are all deleted.
4. Restart the WebSphere_Portal server and then navigate back to the Search Collections page to verify that all search collections have been deleted.

**Parent topic:** Preparing the primary node on AIX

**Previous topic:** Configuring the primary node to communicate with the deployment manager on AIX
Choosing the type of cluster to create on AIX

If you installed a IBM® WebSphere® Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX

Choose one of the following options to create a cluster:

- **Creating a static cluster on AIX**
  After installing IBM WebSphere Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

- **Creating a new dynamic cluster on AIX using WebSphere Virtual Enterprise**
  After installing and configuring IBM WebSphere Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

**Parent topic:** Setting up a cluster on AIX  
**Previous topic:** Preparing the primary node on AIX  
**Next topic:** Preparing a remote Web server when portal is installed on AIX
Creating a static cluster on AIX

After installing IBM® WebSphere® Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

Perform the following steps to create the cluster:

1. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.

   **Important:** Ensure that you set `WasUserid` and `WasPassword` to the Deployment Manager user ID and password.

2. Stop the `server1` and `WebSphere_Portal` servers on the primary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory:

   **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.

   A. Set `WasSoapPort` to the port used to connect remotely to the deployment manager.
   B. Set `WasRemoteHostName` to the full host name of the server used to remotely connect to the deployment manager.
   C. Verify that `WasPassword` is set to your deployment manager password.
   D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   E. Verify that `ClusterName` is set.
   F. Verify that `PrimaryNode` is set to `true`.

3. Make a backup copy of the `wp_profile_root/config/cells/cell_name/wim/config/wimconfig.xml` and `wp_profile_root/config/cells/cell_name/wim/model/wimxmlextension.xml`, if available, files.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the primary node.

   **Note:** If you want to specify custom ports for the nodeagent, add the `DPortPropsFile=full to portsfile` parameter to the `cluster-node-config-pre-federation` task. You can use the ports files that are found on the Setup CD for `WebSphere_Portal` and `server1` as a guide.

   **Note:** You may receive a message about accepting an SSL signer certificate. Failure to accept the SSL signer certificate will cause the script to fail. Alternatively, the `com.ibm.ssl.enableSignerExchangePrompt` flag can be enabled in the `ssl.client.props` file for "DefaultSSLSettings" in order to allow acceptance of the signer during the connection attempt.

   **Warning:** If the `cluster-node-config-pre-federation` fails for any reason, you must perform the following steps before rerunning the task:

   A. Remove the node if the `AddNode` task succeeded.
   B. Log on to the deployment manager and perform the following steps if the items exist:
      1. Remove all enterprise applications.
      2. Remove the `WebSphere_Portal` server definition.
      3. Remove the WebSphere Portal JDBC Provider.

   **Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following technote: Migrating with Lookaside Data.
5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.

**Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db DbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWaspPassword=dmgr_password -DDDBDomain=la|federated db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

**Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

6. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWaspPassword=dmgr_password` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWaspPassword=password -DNewAdminId=newadminid -DNewAdminPw=newpassword -DNewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for `-DWaspPassword` is the Deployment Manager administrative password.

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWaspPassword=dmgr_password` task.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DNewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWaspPassword=dmgr_password` task.

9. Configure the cluster to use an external Web server to take advantage of features such as workload management.

Choose one of the following options:

- Configuring a Web server and an application server on separate machines (remote)
- Configuring a Web server and an application server profile on the same machine
- Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard.

10. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.
B. Select Environment > WebSphere Variables.

C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.

D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.

G. Log off of the deployment manager administrative console.

11. Run the following tasks to propagate your changes: **Note:** WebSphere_Portal_nodename is the name of the node's WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the serverstatus -all task to get a list of the server names and their status.

A. ./stopManager.sh -username admin_userid -password admin_password, from the dmgr_profile_root/bin directory

B. ./stopNode.sh -username admin_userid -password admin_password, from the wp_profile_root/bin directory

C. ./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password

D. ./startManager.sh, from the dmgr_profile_root/bin directory

E. ./startNode.sh, from the wp_profile_root/bin directory

F. ./startServer.sh WebSphere_Portal_nodename

12. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

</tr>
</tbody>
</table>

**Parent topic:** Choosing the type of cluster to create on AIX

**Related tasks**

- Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Creating a new dynamic cluster on AIX using WebSphere Virtual Enterprise

After installing and configuring IBM® WebSphere® Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

Before creating your dynamic cluster, install and configure the Deployment Manager and perform all the tasks under “Preparing the primary node.” On the Deployment Manager system, install WebSphere Virtual Enterprise and augment the deployment manager profile. On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- Prerequisites
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
    - Augmenting profiles

Perform the following steps to create a dynamic cluster:

1. Perform the following steps for on the primary node of the dynamic cluster:
   A. Prepare the node for the dynamic cluster; perform all tasks under Preparing the primary node.
   B. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   C. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
      1. Set WasSoapPort to the port used to connect remotely to the deployment manager.
      2. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
      3. Verify that WasPassword is set to your deployment manager password.
      4. Verify that PortalAdminPwd is set to your WebSphere Portal password.
      5. Verify that ClusterName is set.
      6. Verify that PrimaryNode is set to true.
   D. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.

   Warning: If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:
   1. Remove the node if the AddNode task succeeded.
   2. Log on to the deployment manager and perform the following steps if the items exist:
      A. Remove all enterprise applications.
      B. Remove the WebSphere_Portal server definition.
      C. Remove the WebSphere Portal JDBC Provider.

   Note: If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following
E. Run the following task. Include each node name as a comma separated list in the command:

1. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file. **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

2. Run the
```
./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDBDomain=la/federated.db -DVmmNodeName=node_name -Ddb_type.NodeDbLibrary=local full path of the database jars
```
task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

F. Run the
```
./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password
```
task.

G. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the
```
./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid
```
task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-dynamic-cluster-setup` task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

2. Log on to the deployment manager administrative console.

3. Perform the following steps to create a node group:
   A. Click **System administration > Node groups**.
   B. Click **New**.
   C. Type the node group **Name**.
   D. Optional: Type any information about the node group in the **Description** text box.
   E. Click **OK**.
   F. Click the **Save** link to save your changes to the master configuration.

4. Perform the following steps to add members to the node group:
   A. Click **System administration > Node groups**.
   B. Click on the name of the node group that you want to add members to.
   C. Click **Node group members** under Additional Properties.
   D. Click **Add**.
   E. Select the primary node and then click **Add**.
   F. Click the **Save** link to save your changes to the master configuration.

5. Perform the following steps to create a dynamic cluster in the node group:
   A. Click **Servers > Dynamic clusters**.
   B. Click **New**.
C. Select WebSphere Application Server from the Server Type pull-down menu and then click Next.
D. Type the cluster name in the Dynamic cluster name text box and then click Next. Type the same value that you provided for the ClusterName parameter in the wkplc.properties file of your primary node.
E. Remove all default membership policies and then click Subexpression builder.
F. Enter the following information in the Subexpression builder window:
   1. Select and from the Logical operator pull-down menu.
   2. Select Nodegroup from the Select operand pull-down menu.
   3. Select Equals (=) from the Operator pull-down menu.
   4. Type the nodegroup name you created in the previous step in the Value text box.
   5. Click Generate subexpression.
   6. Click Append.
G. Click Preview membership to verify that all nodes included in the nodegroup display and then click Next.
H. Click the Create the cluster member using an existing server as a template radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu.
I. Click Next.
J. Specify the dynamic cluster properties and then click Next.
K. Review the summary page to verify your actions and then click Finish.
L. Click the Save link to save your changes to the master configuration.

6. Define or verify the following parameters in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:

   A. Set ClusterName to the name of the new dynamic cluster.
   B. Verify that CellName is set to the deployment manager cell.
   C. Verify that NodeName is set to the local WebSphere Portal node.
   D. Set ServerName to the server that will be used for the dynamic cluster member on this node.

       Note: Log on to the deployment manager administrative console and click Dynamic Clusters > PortalCluster > Dynamic cluster members to find the name of the server used for the dynamic cluster.
   E. Verify that PrimaryNode is set to true.

7. Run the ./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the dynamic cluster.

       Note: This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

8. Perform the following steps to access the Web Content Management content through an external Web server:

   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Reresynchronize.
   G. Log off of the deployment manager administrative console.

9. Run the following tasks to propagate your changes:

       Note: WebSphere_Portal_nodename is the name of the node's WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the
server name, run the `serverstatus -all` task to get a list of the server names and their status.

A. `./stopManager.sh -username admin_userid -password admin_password`, from the `dmgr_profile_root/bin` directory
B. `./stopNode.sh -username admin_userid -password admin_password`, from the `wp_profile_root/bin` directory
C. `./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`
D. `./startManager.sh`, from the `dmgr_profile_root/bin` directory
E. `./startNode.sh`, from the `wp_profile_root/bin` directory
F. `./startServer.sh WebSphere_Portal_nodename`

**Parent topic:** Choosing the type of cluster to create on AIX
Preparing a remote Web server when portal is installed on AIX

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- Prerequisites
  - Preparing the WebSphere Application Server Deployment Manager on AIX
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the $NOTES.INI$ file on the Web server. Set the $HTTPEnableConnectorHeaders$ parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the $httpd.conf$ file on the Web server. Set the $AllowEncodedSlashes$ directive to on; the directive should be added at the root level as a global directive.
4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. Note: The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

   If using WebDAV: After successfully installing the Web server plug-in, locate and open your $plugin-cfg.xml$ file and set $AcceptAllContent$ to true.

   Important: Depending on how you use the Web server, you may need to adjust the $ServerIOTimeout$ value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your $plugin-cfg.xml$ file and set $ServerIOTimeout$ to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.
6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.
Next topic: Configuring WebSphere Portal to use a user registry on AIX in a clustered environment
Configuring WebSphere Portal to use a user registry on AIX in a clustered environment

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- Prerequisites
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX

Perform the following tasks to configure WebSphere Portal to use a user registry:

1. Preparing user registries on AIX
   Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

2. Choosing your user registry model on AIX in a clustered environment
   Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Parent topic: Setting up a cluster on AIX

Previous topic: Preparing a remote Web server when portal is installed on AIX

Next topic: Preparing additional nodes on AIX
Preparing user registries on AIX

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

Choose the appropriate LDAP server to install and setup:

- **Preparing a Domino Directory server**
  If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a SecureWay Security Server**
  If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Novell eDirectory**
  If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Sun Java System Directory Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Tivoli Directory Server**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

**Parent topic:** Configuring WebSphere Portal to use a user registry on AIX in a clustered environment

**Next topic:** Choosing your user registry model on AIX in a clustered environment
Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Domino Directory:

1. Perform the following steps to install the Domino Directory:
   A. Go to Lotus Domino documentation.
   B. Select the appropriate version tab for your product.
   C. Click the Download/View online link for the Lotus Domino for multiple platforms Information Center.
   D. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > Server installation > Installing Domino on Unix and perform this task.
   E. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > The Domino server setup program and perform this task.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Navigate to the People view of the Domino Directory and then click Add Person.
   B. Enter the following values in the New Person form to create the wpsbind user:
      - Last Name
        - wpsbind
      - User Name
        - wpsbind/Domain, where Domain is your Lotus Domino Internet domain
        - wpsbind
        Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsbind
      - Internet password
        - wpsbind
   C. Click Save and Close to save the new person record for wpsbind and return to the People view.
   D. Click Add Person and enter the following values in the New Person form to create the wpsadmin user:
      - Last Name
        - wpsadmin, where wpsadmin in the user ID for the WebSphere Portal Administrator
      - User Name
        - wpsadmin/Domain, where Domain is your Lotus Domino Internet domain
        - wpsadmin
        Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsadmin
      - Internet password
        - wpsadmin
   E. Click Save and Close to save the new person record for wpsadmin and return to the People view.
   F. Navigate to the Groups view and click Add Group.
   G. Enter the following values in the New Group form on the Basic tab:
      - Group name
- **wpsadmins**
  - **Note:** If you plan to configure WebSphere Portal for multiple user registries and your Lotus Domino LDAP will share a realm with another user registry, you must use the hierarchical naming convention for the group names, for example: wpsadmins/DominoDomain, to avoid unexpected results during WebSphere Portal runtime.

- **Group type**
  - Multi-purpose

- **Members**
  - wpsbind/DominoDomain
  - wpsadmin/DominoDomain
  - **Note:** You can add additional administrator users if required.

H. Click **Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

3. Perform the following steps to update the access control list for the Domino Directory:
   A. Open the names.nsf file in the Lotus Domino Administrator or Lotus Notes client.
   B. Click **File > Application > Access Control** from the main menu to open the access control list for the file.
   C. In the **Access Control List > Basics** panel, ensure that the wpsadmins group has either Author or Editor access.
   D. Add the following Role Types to the wpsadmins group:
      - GroupCreator
      - GroupModifier
      - UserCreator
      - UserModifier
   E. Click **OK**.

*Parent topic:* Preparing user registries on AIX
Preparing a SecureWay Security Server

If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare SecureWay Security Server:

1. Install SecureWay Security Server; refer to the IBM SecureWay™ Security Server for z/OS® and OS/390® for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on AIX
Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Novell eDirectory:

1. Install Novell eDirectory; refer to eDirectory for information.
2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on AIX
Preparing a Sun Java System Directory Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: `dc=yourcompany,dc=com`.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every `dc=yourco,dc=com` with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.

3. Follow the instructions provided with your directory server to import the LDIF file.
4. Stop and restart the LDAP server.

Parent topic:Preparing user registries on AIX
Preparing a Tivoli Directory Server

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

   
   **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:
   
   - Optional: Perform the following steps to create a new directory suffix:
     
     1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
     2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
     3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
     4. Click **Add**.
     5. Click **OK** to save your changes.
     6. Stop and restart the LDAP server.

   - Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
     
     - Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.
     - Use the `ContentUsers.ldif` file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   - Replace every `dc=yourco,dc=com` with your suffix.

   - Replace any prefixes and suffixes that are unique to your LDAP server.

   - You can specify user names other than `wpsadmin` and `wpsbind`. For security reasons, specify nontrivial passwords for these administrator accounts.

   - Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to `accessGroup`. If using Tivoli Access Manager Version 6, set the **objectclasses** to `groupOfNames`.

   - Save your changes.

   - Follow the instructions provided with your directory server to import the LDIF file.

   - Stop and restart the LDAP server.

Parent topic: Preparing user registries on AIX
Choosing your user registry model on AIX in a clustered environment

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on AIX in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on AIX in a clustered environment**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

- **Adapting the attribute configuration**
  After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

**Parent topic:** Configuring WebSphere Portal to use a user registry on AIX in a clustered environment

**Previous topic:** Preparing user registries on AIX
Configuring a stand-alone LDAP user registry on AIX in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on AIX in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on AIX in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on AIX in a clustered environment
Configuring a stand-alone LDAP user registry on AIX in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the wp-modify-ldap-security task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the standalone.ldap.realm parameter or you can set ignoreDuplicateIDs=true in the wkplc.properties file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Stand-alone LDAP configuration heading:

   - standalone.ldap.id
   - standalone.ldap.host
   - standalone.ldap.port
   - standalone.ldap.blindDN
   - standalone.ldap.bindPassword
   - standalone.ldap.ldapServerType
   - standalone.ldap.userIdMap
   - standalone.ldap.groupIdMap
   - standalone.ldap.groupMemberIdMap
   - standalone.ldap.userFilter
   - standalone.ldap.groupFilter
   - standalone.ldap.serverId
   - standalone.ldap.serverPassword
   - standalone.ldap.realm
   - standalone.ldap.primaryAdminId
   - standalone.ldap.primaryAdminPassword
   - standalone.ldap.primaryPortalAdminId
   - standalone.ldap.primaryPortalAdminPassword
   - standalone.ldap.primaryPortalAdminGroup
   - standalone.ldap.baseDN
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading:
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.et.group.objectClasses`
   - `standalone.ldap.et.group.objectClassesForCreate`
   - `standalone.ldap.et.group.searchBases`
   - `standalone.ldap.et.personaccount.objectClasses`
   - `standalone.ldap.et.personaccount.objectClassesForCreate`
   - `standalone.ldap.et.personaccount.searchBases`

4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading:
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.gm.groupMemberName`
   - `standalone.ldap.gm.objectClass`
   - `standalone.ldap.gm.scope`
   - `standalone.ldap.gm.dummyMember`

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading:
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.personAccountParent`
   - `standalone.ldap.groupParent`
   - `standalone.ldap.personAccountRdnProperties`
   - `standalone.ldap.groupRdnProperties`

6. Save your changes to the `wkplc.properties` file.

7. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product.
   Note: See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.
   - `WcmContentAuthorsGroupId`
   - `WcmContentAuthorsGroupCN`

8. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=(password)` task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.
   Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

9. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=(password)` task, from the `wp_profile_root/ConfigEngine` directory, to set the stand-alone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=(password)` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. Important: When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

   `uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN`

   Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action=express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root`/ConfigEngine directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See **Enabling LDAP security after cluster creation** for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on AIX in a clustered environment

**Related tasks**

- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring a stand-alone LDAP user registry over SSL on AIX in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: NodeDefaultSSLSettings
           - Clustered environments: CellDefaultSSLSettings
           **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
        4. Click Key stores and certificates.
        5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
        6. Click Signer certificates, click Add, and then enter the following information:
           - Type the Alias the key store uses for the signer certificate.
           - Type the File name where the signer certificate is located.
        7. Click OK and then click Save to save the changes to the master configuration.
   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
      2. Navigate to Security > SSL certificate and key management > SSL configurations.
      3. Click the appropriate SSL configuration from the list. For example,
Clustered environments: CellDefaultSSLSettings

Clustered environments: Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

4. Click Key stores and certificates.

5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.

6. Click Signer certificates, click Retrieve from port, and then enter the following information:
   - Type the Host name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL Port used when attempting to retrieve the signer certificate.
   - Type the Alias the key store uses for the signer certificate.

7. Click Retrieve signer information to retrieve the certificate from the port.

8. Click OK and then click Save to save the changes to the master configuration.

- Client trust storeNote: This task might report an error, but it does successfully update the trust store. You can ignore the error message.
  A. See Secure installation for client signer retrieval.
  B. Run the retrieveSigners task from the wp_profile_root/bin directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:
   1. Use a text editor to open the ssl.client.props file, located in the wp_profile_root/properties directory.
   2. Change the com.ibm.ssl.trustStore parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12 to use the default trust store.
   3. Save your changes.

2. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Stand-alone LDAP configuration heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.idap.id
   - standalone.idap.host
   - standalone.idap.port
   - standalone.idap.blndDN
   - standalone.idap.bindPassword
   - standalone.idap.idapServerType
   - standalone.idap.userldMap
   - standalone.idap.groupIdMap
   - standalone.idap.groupMemberIdMap
   - standalone.idap.userFilter
   - standalone.idap.groupFilter
   - standalone.idap.serverId
   - standalone.idap.serverPassword
   - standalone.idap.realm
   - standalone.idap.prlmaryAdminId
   - standalone.idap.prlmaryAdminPassword
   - standalone.idap.prlmaryPortalAdminId

1231
4. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.et.group.objectClasses
   - standalone.ldap.et.group.objectClassesForCreate
   - standalone.ldap.et.group.searchBases
   - standalone.ldap.et.personaccount.objectClasses
   - standalone.ldap.et.personaccount.objectClassesForCreate
   - standalone.ldap.et.personaccount.searchBases

5. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attributes heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.gm.groupMemberName
   - standalone.ldap.gm.objectClass
   - standalone.ldap.gm.scope
   - standalone.ldap.gm.dummyMember

6. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the wkplc.properties file under the Default parent, RDN attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.personAccountParent
   - standalone.ldap.groupParent
   - standalone.ldap.personAccountRdnProperties
   - standalone.ldap.groupRdnProperties

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL): **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   Required parameters:
   - standalone.ldap.sslEnabled
   - standalone.ldap.sslConfiguration

   Optional parameters:
   - standalone.ldap.certificateMapMode
   - standalone.ldap.certificateFilter

8. Save your changes to the wkplc.properties file.

9. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, **WasPassword** is the value entered during installation and not a value found in your LDAP user registry.
   **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press `y` then **Enter**.

10. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set the stand-alone LDAP user registry.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: **Starting and stopping servers, deployment managers, and node agents.**

12. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured...
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on AIX in a clustered environment

**Related tasks**
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring the default federated repository on AIX in a clustered environment

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on AIX in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on AIX in a clustered environment**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on AIX in a clustered environment**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

**Parent topic:** Choosing your user registry model on AIX in a clustered environment
Configuring a federated LDAP user registry on AIX in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Adding an LDAP user registry on AIX in a clustered environment**
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName, o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

- **Adding an LDAP user registry over SSL on AIX in a clustered environment**
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

**Parent topic:** Configuring the default federated repository on AIX in a clustered environment
Adding an LDAP user registry on AIX in a clustered environment

Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM® Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName,o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root` /ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.id`
   - `federated.ldap.host`
   - `federated.ldap.port`
   - `federated.ldap.bindDN`
   - `federated.ldap.bindPassword`
   - `federated.ldap.ldapServerType`
   - `federated.ldap.baseDN`

3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.et.group.objectClasses`
   - `federated.ldap.et.group.objectClassesForCreate`
   - `federated.ldap.et.group.searchBases`
   - `federated.ldap.et.personaccount.objectClasses`
- `federated.ldap.et.personaccount.objectClassesForCreate`
- `federated.ldap.et.personaccount.searchBases`

4. **Required:** Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attribute heading:
   
   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   
   - `federated.ldap.gm.groupMemberName`
   - `federated.ldap.gm.objectClass`
   - `federated.ldap.gm.scope`
   - `federated.ldap.gm.dummyMember`

5. Save your changes to the `wkplc.properties` file.

6. Run the `./ConfigEngine.sh validate-federated-ldap -DWasPassword=password` task to validate your LDAP server settings.
   
   **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.
   
   **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?.
   
   Press **y** then **Enter**.

7. Run the `./ConfigEngine.sh wp-create-ldap -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add an LDAP user registry to the default federated repository.
   
   **Note:** Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: "Starting and stopping servers, deployment managers, and node agents."

9. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
   
   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
   
   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:
      
      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
      
      - `id`
      - `baseDN`
      - `nameInRepository`
   
   C. Save your changes to the `wkplc.properties` file.
   
   D. Run the `./ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to create a base entry in a repository.
   
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

11. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Perform the following steps to update the user registry where new users and groups are stored:
   
   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties`
and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

   - `personAccountParent`
   - `groupParent`
   - `personAccountRdnProperties`
   - `groupRdnProperties`

   The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:
   - `personAccountParent=dc=yourco,dc=com`
   - `groupParent=dc=yourco,dc=com`

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for `realmName` or leave blank to update the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

B. Add the following lines to the file:

   ```
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
   ```

   Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: **Table 1. Value for realm_name when running the Member Fixer task to update the member names**
15. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

16. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   **Important:**
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

   **Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

   A. Run the following task from the `wp_profile_root/ConfigEngine` directory:

   ```bash
   .ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword
   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.
   ```

   B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

   C. Run the following task from the `wp_profile_root/ConfigEngine` directory:

   ```bash
   .ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid
   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.
   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.
   ```

   D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

17. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: Deleting the repository.

   If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

Adding an LDAP user registry over SSL on AIX in a clustered environment

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to **Security > SSL certificate and key management > SSL configurations**.
        3. Click the appropriate SSL configuration from the list. For example,
           - **Stand-alone environments**: `NodeDefaultSSLSettings`
           - **Clustered environments**: `CellDefaultSSLSettings`
        4. **Clustered environments**: Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.
        5. Click **Key stores and certificates**.
        6. Click **Signer certificates**, click **Add**, and then enter the following information:
           - Type the **Alias** the key store uses for the signer certificate.
           - Type the **File name** where the signer certificate is located.
        7. Click **OK** and then click **Save** to save the changes to the master configuration.
     B. Retrieve the certificate from the port:
        1. Log in to the WebSphere Application Server Administrative Console.
2. Navigate to **Security > SSL certificate and key management > SSL configurations**.
3. Click the appropriate SSL configuration from the list. For example,
   - Stand-alone environments: **NodeDefaultSSLSettings**
   - Clustered environments: **CellDefaultSSLSettings**

   **Clustered environments:** Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.
4. Click **Key stores and certificates**.
5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.
6. Click **Signer certificates**. Click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the **SSL Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.
7. Click **Retrieve signer information** to retrieve the certificate from the port.
8. Click **OK** and then click **Save** to save the changes to the master configuration.

   **Client trust store**
   - **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

   **A.** See **Secure installation for client signer retrieval**.

   **B.** Run the **retrieveSigners** task from the **wp_profile_root/bin** directory; see **retrieveSigners command** for information. In a deployed environment, you will need to run the **retrieveSigners** task, for any federated node, against the **Deployment Manager**.

   **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

   **C.** Update the trust store properties file:
   1. Use a text editor to open the **ssl.client.props** file, located in the **wp_profile_root/properties** directory.
   2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter

      com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12 to use the default trust store.

   3. Save your changes.

2. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory.
3. Required: Enter a value for the following required parameters in the **wkplc.properties** file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - **federated.idap.id**
   - **federated.idap.host**
   - **federated.idap.port**
   - **federated.idap.bindDN**
   - **federated.idap.bindPassword**
   - **federated.idap.IdapServerType**
   - **federated.idap.baseDN**

4. Required: Enter a value for the following required entity types parameters in the **wkplc.properties** file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - **federated.idap.et.group.objectClasses**
   - **federated.idap.et.group.objectClassesForCreate**
   - **federated.idap.et.group.searchBases**
- federated.ldap.et.personaccount.objectClasses
- federated.ldap.et.personaccount.objectClassesForCreate
- federated.ldap.et.personaccount.searchBases

5. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attribute heading:
   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

- federated.ldap.gm.groupMemberName
- federated.ldap.gm.objectClass
- federated.ldap.gm.scope
- federated.ldap.gm.dummyMember

6. Enter a value for the following parameters to enable Secure Socket Layers (SSL): **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   Required parameters:
   - federated.ldap.sslEnabled
   - federated.ldap.sslConfiguration

   Optional parameters:
   - federated.ldap.certificateMapMode
   - federated.ldap.certificateFilter

7. Save your changes to the `wkplc.properties` file.

8. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. **Note:** See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.

- WcmContentAuthorsGroupId
- WcmContentAuthorsGroupCN

9. Run the `./ConfigEngine.sh validate-federated-ldap -DWasPassword=\password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.

   **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press `y` then `Enter`.

10. Run the `./ConfigEngine.sh wp-create-ldap -DWasPassword=\password` task, from the `wp_profile_root/ConfigEngine` directory, to add an LDAP user registry to the default federated repository. **Note:** Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

12. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:

   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh \ wp-create-base-entry -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Run the \texttt{./ConfigEngine.sh \ wp-query-repository -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to list the names and types of configured repositories.

14. Run the \texttt{./ConfigEngine.sh \ wp-validate-federated-ldap-attribute-config -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to check that all defined attributes are available in the configured LDAP user registry.\textbf{Important:} When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

15. Perform the following steps to update the user registry where new users and groups are stored:

\textbf{Note:} If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

\textbf{Attention:} During installation, the default file repository creates a default value in the \texttt{personAccountRdnProperties} and \texttt{groupRdnProperties} parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root/ConfigEngine/properties} directory.

B. Enter a value for the following required parameters in the \texttt{wkplc.properties} file under the VMM supported entity types configuration heading:

\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{personAccountParent}
- \texttt{groupParent}
- \texttt{personAccountRdnProperties}
- \texttt{groupRdnProperties}

The parameters \texttt{groupParent} and \texttt{personAccountParent} must be set to the same value. For example:

- \texttt{personAccountParent=dc=yourco,dc=com}
- \texttt{groupParent=dc=yourco,dc=com}

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh \ wp-set-entitytypes -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to delete the old attributes before adding the new attributes.

E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root/ConfigEngine/properties} directory.

B. Enter a value for \texttt{realmName} or leave blank to update the default realm.

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh \ wp-modify-realm-enable-dn-login -DWasPassword=password} task, located in the \texttt{wp_profile_root/ConfigEngine} directory, to enable the distinguished name login.\textbf{Note:} After running this task to enable the full distinguished name login, you can run the \texttt{./ConfigEngine.sh \ wp-modify-realm-disable-dn-login -DWasPassword=password} task to disable the feature.
17. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

Note: This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the configure-express task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. Note: Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the wkplc.properties file. If the value for <code>federated.realm</code> is empty, use defaultWIMFileBasedRealm as the default value.</td>
</tr>
</tbody>
</table>

18. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

19. Optional: This step is required in a production environment. Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   Important:
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

Note: If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root/ConfigEngine` directory: `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword` Important: You must provide the full distinguished name (DN) for the `newAdminId` parameter.
B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine` directory:
```
./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid
```

**Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `--skip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

20. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a federated LDAP user registry on AIX in a clustered environment

**Related tasks**

- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation

**Related information**

- User IDs and passwords
Adding a database user registry on AIX in a clustered environment

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you have WebSphere Application Server Version 7.0.x installed, you must install APAR PM23090 and APAR PM24181 for WebSphere Portal prior to running this task. Clusters with WebSphere Application Server Version 6.1.x do not require these APARs.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_DB.properties` helper file, located in the `/wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_DB.properties` helper file.

1. Set up a new database, including creating a new user with appropriate database privileges for accessing the database:
   - **Instructions for setting up databases:** Refer to the appropriate documentation for the type of database you want to set up.
   - **Consulting your database administrator:** The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

   **Table 1. Steps for creating a new database to use as a database user registry.**

<table>
<thead>
<tr>
<th>Database</th>
<th>Steps</th>
</tr>
</thead>
</table>

1247
### DB2
Perform the following steps to create a DB2 database:
- Install DB2.
- Enter the following database tuning commands:
  ```
  CREATE DB dbname using codeset UTF-8
territory us PAGESIZE 8192
  UPDATE DB CFG FOR dbname USING
  applheapsz 4096
  UPDATE DB CFG FOR dbname USING
  app_ctl_heap_sz 1024
  UPDATE DB CFG FOR dbname USING
  stmtheap 32768
  UPDATE DB CFG FOR dbname USING
  dbheap 2400
  UPDATE DB CFG FOR dbname USING
  locklist 1000
  UPDATE DB CFG FOR dbname USING
  logfilsz 4000
  UPDATE DB CFG FOR dbname USING
  logprimary 12
  UPDATE DB CFG FOR dbname USING
  logsecondary 20
  UPDATE DB CFG FOR dbname USING
  logbufsz 32
  UPDATE DB CFG FOR dbname USING
  avg_appls 5
  UPDATE DB CFG FOR dbname USING
  locktimeout 30
  UPDATE DB CFG FOR dbname using
  AUTO_MAINT off
  ```

### Oracle
Perform the following steps to create an Oracle database:
- Install Oracle using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- Configure the database in Dedicated Server Mode.
- Enter the recommended initial buffer pool sizes or set them according to your business needs:
  - `db_block_size = 8192`
  - `db_cache_size = 300M`
  - `db_files = 1024`
  - `log_buffer = 65536`
  - `open_cursors = 1500`
  - `pga_aggregate_target = 200M`
  - `pre_page_sga = true`
  - `processes = 300`
  - `shared_pool_size = 200M`

### SQL Server
Perform the following steps to create an SQL Server database:
- Install SQL Server.
- Set Collation to case-sensitive.

**Note:** Install SQL Server with the appropriate portal database collation so that your tempdb collation setting matches the collation you use for the property extension database. The tempdb collation is inherited from the master database, which you set when you install SQL Server.

2. Perform the following steps to define the **DbDriver** and **DbLibrary** parameter values:
   A. Navigate to the following directory: `wp_profile_root/ConfigEngine/properties`
   B. Locate and open `wkplc_dbtype.properties` with any text editor.
   C. Enter a value for the following parameters under the appropriate database type properties heading:
      - `db_type.DbDriver`
      - `db_type.DbLibrary`
   D. Save your changes.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated Database Properties heading:
   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
5. Change the value for the `com.ibm.SOAP.requestTimeout` parameter to 1000.

   A. Navigate to the following directory: `wp_profile_root/properties`
   B. Locate and open `soap.client.props` with any text editor.
   C. Locate the `com.ibm.SOAP.requestTimeout` parameter and change the value to 1000.
   D. Save and close `soap.client.props`.

6. Perform the following steps in a clustered environment:

   A. Run the `./ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=password` task from the `wp_profile_root/ConfigEngine` directory to create the local Deployment Manager WebSphere variable used to access the database jars. **Note:** The `db_type` in `db_type.DmgrDbLibrary` should be set to the type of database you are using, for example `db2`. The `local full path of the database jars on the Deployment Manager` should be one of the following options:

   - **DB2 Type 2 driver:** `db2java.zip`
   - **DB2 Type 4 driver:** `db2jcc.jar;db2jcc_license_cu.jar`
   - **DB2 for z/OS Type 2 driver:** `db2java.zip`
   - **DB2 for z/OS Type 4 driver:** `db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar`
   - **Oracle:** `ojdbc14.jar`
   - **SQL Server JDBC driver provided by Microsoft:** `sqljdbc.jar`
   - **SQL Server JDBC driver provided by DataDirect:** `sqlserver.jar;base.jar;util.jar`

   B. Run the following task. Include each node name as a comma separated list in the command:

   **Running the task:** You do not have to run this task more than once. You can run this task from any node in the cluster.

   1. Set the property value for `federated.db.DbType` in the `wkpcl.properties` file if using a database user registry.
   2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=password -DbDomain=federated.db -Db_type.DmgrDbLibrary=local full path of the database jars on the Deployment Manager -DNodeDbName=dmgr_node_name` task from the `wp_profile_root/ConfigEngine` directory on each node to create the variable used to access the VMM database jars. **Note:** The `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.
   C. Stop and restart all necessary servers to propagate your changes.

7. Run the `./ConfigEngine.sh wp-create-db -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add a database user registry to the default federated repository. **Note:** Users who are not in an LDAP do...
not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the **personAccountRdnProperties** and **groupRdnProperties** parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory.

   B. Enter a value for the following required parameters in the **wkplc.properties** file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - **personAccountParent**
      - **groupParent**
      - **personAccountRdnProperties**
      - **groupRdnProperties**

      The parameters **groupParent** and **personAccountParent** must be set to the same value. For example:

      - **personAccountParent=dc=yourco,dc=com**
      - **groupParent=dc=yourco,dc=com**

   C. Save your changes to the **wkplc.properties** file.

   D. Run the **./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password** task, from the **wp_profile_root/ConfigEngine** directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the **./ConfigEngine.sh wp-query-repository -DWasPassword=password** task, from the **wp_profile_root/ConfigEngine** directory, to list the names and types of configured repositories.

    If you created your clustered environment then performed the steps in this task, you must now run the **enable-jcr-security** task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

**Parent topic:** Configuring the default federated repository on AIX in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Adding realm support on AIX in a clustered environment

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
   - realmName
   - securityUse
   - delimiter
   - addBaseEntry
   Note: See the properties file for specific information about the required parameters and for advanced parameters.

3. Save your changes to the wkplc.properties file.

4. Run the ./ConfigEngine.sh wp-create-realm -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add a new realm to the Virtual Member Manager configuration. Important: To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the wkplc.properties file with the base entry information and rerun the wp-create-realm task. Repeat these steps until all realms are created.

5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

6. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading and then save your changes:
   - realmName
   - realm.personAccountParent
   - realm.groupParent
   - realm.orgContainerParent
   Note: See the properties file for specific information about the required parameters and for advanced parameters.

7. Run the ./ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to update the default parents per entity type and realm. Important: Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types.
8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:
   A. Use a text editor to open the wkplc.properties file, located in the `wp_profile_root/ConfigEngine/properties` directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
      - `realmName`
      - `addBaseEntry`
   C. Save your changes to the wkplc.properties file.
   D. Run the `./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add additional LDAP base entries to the realm configuration.
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:
   A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.
   B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.
   C. Create a new group in the Manage Users and Groups portlet to replace the current group.
   D. Run the `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.
   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.
   E. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
   F. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task to replace the old WebSphere Portal administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.
   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.
   G. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

11. Optional: Perform the following steps to set the realm you created as the default realm. **Remember:** Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the `wp-query-realm-baseentry` task to see what base entries are part of the default realm. If the default realm is missing
the base entry, run the \texttt{wp-add-realm-baseentry} task to add the base entry to the default realm.

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root}/ConfigEngine/properties directory.

B. For \texttt{defaultRealmName}, type the \texttt{realmName} property value you want to use as the default realm.

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh wp-default-realm -DWasPassword=password} task, from the \texttt{wp_profile_root}/ConfigEngine directory, to set this realm as the default realm.

E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root}/ConfigEngine/properties directory.

B. For \texttt{realmName}, type the name of the realm you want to query.

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=password} task, from the \texttt{wp_profile_root}/ConfigEngine directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root}/ConfigEngine/properties directory.

B. Enter a value for \texttt{realmName} or leave blank to update the default realm.

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password} task, located in the \texttt{wp_profile_root}/ConfigEngine directory, to enable the distinguished name login. \textbf{Note:} After running this task to enable the full distinguished name login, you can run the \texttt{./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password} task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the \texttt{enable-jcr-security} task on the secondary node. See \textit{Enabling LDAP security after cluster creation} for instructions.

\textbf{Parent topic:} Configuring the default federated repository on AIX in a clustered environment

Adapting the attribute configuration

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. **Querying the defined attributes on AIX**
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. **Adding attributes on AIX in a clustered environment**
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. **Mapping attributes on AIX in a clustered environment**
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. **Removing attributes**
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

**Parent topic:** Choosing your user registry model on AIX in a clustered environment

**Related tasks**
- Adding an LDAP user registry on AIX
- Adding an LDAP user registry over SSL on AIX
- Configuring a stand-alone LDAP user registry on AIX
Configuring a stand-alone LDAP user registry over SSL on AIX
Querying the defined attributes on AIX

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `./ConfigEngine.sh wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (**PersonAccount**) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on AIX in a clustered environment
Adding attributes on AIX in a clustered environment

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file: Table 1. Steps for installing the .ear file by environment

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone environment</td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the <code>wp_profile_root/ConfigEngine</code> directory. Run the <code>./ConfigEngine.sh wp-la-install-ear -DWasPassword=password</code> task.</td>
</tr>
<tr>
<td>Cluttered environment</td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the <code>wp_profile_root/ConfigEngine</code> directory on the primary node. Run the <code>./ConfigEngine.sh wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name</code> task. Where <code>node_name</code> is the name of the node where the deployment manager resides; you can find the <code>node_name</code> value in the WebSphere Application Server Administrative Console under <code>System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name</code>.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Property Extension Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - `la.providerURL`
   - `la.propertyName`
   - `la.entityTypes`
   - `la.dataType`
   - `la.multiValued`

5. Save your changes to the `wkplc.properties` file.

6. Run the `./ConfigEngine.sh wp-add-property -DWasPassword=password` task to add the attribute to the user registry.

   Note: This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere.
Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

**Remember:** If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Adapting the attribute configuration

**Previous topic:** Querying the defined attributes on AIX

**Next topic:** Mapping attributes on AIX in a clustered environment

**Related tasks**
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Mapping attributes on AIX in a clustered environment

After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

Perform the following steps to map attributes between WebSphere Portal and your LDAP server; if you have multiple LDAP servers, you will need to perform these steps for each LDAP server:

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

2. Enter a value for one of the following sets of parameters in the `wkplc.properties` file to identify your LDAP server:
   - **Note:** Make sure you use the same values you used to configure your LDAP server.
   
   Table 1. Identifying your LDAP server in the `wkplc.properties` file.

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:
   - **/ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the `wp_profile_root/ConfigEngine` directory.
   - **/ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password task, from the `wp_profile_root/ConfigEngine` directory.

4. Open the `ConfigTrace.log` file, located in the `wp_profile_root/ConfigEngine/log` directory, to review the following output for the **PersonAccount** and **Group** entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the uid, cn, firstName, sn, preferredLanguage, and ibm-primaryEmail attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

6. Enter a value for one of the following sets of parameters in the wkplc.properties file to correct any issues found in the config trace file: Table 3. Parameters to define in the wkplc.properties file to correct any issues found in the config trace file.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>The following parameters are found under the LDAP attribute configuration heading: <strong>Note:</strong> See the properties file for specific information about the required parameters and for advanced parameters. standalone.idstandalone.ldap.attributes.nonSupportedstandalone.ldap.attributes.nonSupported.deletestandalone.ldap.attributes.mapping.ldapNamestandalone.ldap.attributes.mapping.portalNamestandalone.ldap.attributes.mapping.entityTypes For example, the following values will flag certificate and members as unsupported attributes and will map ibm-primaryEmail to mail and ibm-jobTitle to title for both the PersonAccount and Group entityTypes: standalone.ldap.attributes.nonSupported=certificate, members standalone.ldap.attributes.nonSupported.delete standalone.ldap.attributes.mapping.ldapNamemail, title standalone.ldap.attributes.mapping.portalName=ibm-primaryEmail, ibm-jobTitle standalone.ldap.attributes.mapping.entityTypes=PersonAccount, Group</td>
</tr>
</tbody>
</table>
7. Save your changes to the `wkplc.properties` file.
8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

   Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td><code>./ConfigEngine.sh wp-update-standalone-ldap-attribute-config -DWasPassword=password</code> task, from the <code>wp_profile_root/ConfigEngine</code> directory</td>
</tr>
<tr>
<td>Federated</td>
<td><code>./ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=password</code> task, from the <code>wp_profile_root/ConfigEngine</code> directory</td>
</tr>
</tbody>
</table>

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: `Starting and stopping servers, deployment managers, and node agents`.

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:

   A. Enter a value for the following required parameters in the `wkplc.properties` file: 
      
      ```
      user.attributes.required
      user.attributes.nonsupported
      ```
      
      ```Note:` See the properties file for specific information about the required parameters and for advanced parameters.

   B. Save your changes to the `wkplc.properties` file.

   C. Run the `./ConfigEngine.sh wp-update-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory.

   D. Stop and restart all necessary servers to propagate your changes.

   If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See `Enabling LDAP security after cluster creation` for instructions.

Enabling LDAP security after cluster creation
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database:

**Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.

   A. Open the tool you use to edit your database.
   B. Verify that your attribute name is available in the LAPROP table.
   C. Delete the required attributes from the LAPROP table.
   D. Open the `wimxmlextension.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/model` directory.
   E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <wim:propertySchema
       nsURI="http://www.ibm.com/websphere/wim"
       dataType="String"
       multiValued="true"
       propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   F. Save your changes to the `wimxmlextension.xml` file.
   G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/config` directory.
   H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <config:propertiesNotSupported name="attribute_name"/>
   ```
   I. Save your changes to the `wimconfig.xml` file.
   J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:

   A. Open the `wimxmlextension.xml` file.
   B. Locate and delete the `propertySchema` definition for the attributes you previously added; for example:

   ```xml
   <wim:propertySchema
       nsURI="http://www.ibm.com/websphere/wim"
       dataType="String"
       multiValued="true"
       propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   C. Save your changes to the `wimxmlextension.xml` file.
   D. Open the `wimconfig.xml` file.
   E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:

   ```xml
   <config:attributes
       name="attribute_name"
       propertyName="property_name"/>
   ```
   F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

**Parent topic:** Adapting the attribute configuration

**Previous topic:** Mapping attributes on AIX in a clustered environment
Preparing additional nodes on AIX

After installing and configuring your primary node, you can create your secondary nodes. You must install IBM® WebSphere® Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX
  - Installing a secondary node after migrating from previous version

Perform the following tasks to prepare your secondary node:

1. **Installing WebSphere Portal on AIX on the additional nodes**
   Install IBM WebSphere Portal on your secondary nodes to create a highly available and scalable environment.

2. **Choosing the type of additional node to create on AIX**
   If you created a static cluster using the IBM WebSphere Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

3. **Choosing the type of vertical cluster to create on AIX**
   If you are using the IBM WebSphere Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

**Parent topic:** Setting up a cluster on AIX

**Previous topic:** Configuring WebSphere Portal to use a user registry on AIX in a clustered environment

**Next topic:** Tune your servers
Installing WebSphere Portal on AIX on the additional nodes

Install IBM® WebSphere® Portal on your secondary nodes to create a highly available and scalable environment.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. **Note:** If you plan to use IBM WebSphere Application Server Version 7.0, you must purchase and install it before installing WebSphere Portal on the existing WebSphere Application Server Version 7.0 instance.

Perform the following steps to install WebSphere Portal:

1. **Type ping yourserver.yourcompany.com on a command line to verify that your fully qualified host name is properly configured.**

2. **If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:**
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities

3. **Optional:** Perform the following steps if you want to install WebSphere Portal using a non-root user:
   - **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   - **A.** Install the current supported version of WebSphere Application Server as a root user.
   - **B.** Open a command prompt and perform the following steps to create a non-root user and to change ownership:

   1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
   2. Run the following tasks to change the rights of the non-root user:

   ```
   chmod -R g+rwx /opt/IBM
   chgrp -R group_name /opt/IBM
   chmod -R g+wr /tmp
   chgrp -R group_name /tmp
   chmod -R g+wr /var/tmp
   ```
C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

4. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

**Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

**Restriction:** When defining your installation path, the **ONLY** supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

### Option Description

<table>
<thead>
<tr>
<th>Graphical user interface</th>
<th>./install.sh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Console mode</td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td>Silent Install</td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. <strong>Important:</strong> Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

5. Verify your installation was successful; access WebSphere Portal using the http://yourserver:yourport/wps/portal format. Run the ../ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root /ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

6. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

**Note:** The starting port parameter is required for a successful completion of the modify-ports-by-startport task. Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

A. Stop the server1 and WebSphere_Portal servers.

B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>.ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

7. Perform the following steps if you migrated from a previous version of WebSphere Portal:
   A. Log on to the WebSphere Application Server Administrative Console.
   C. Click WP Identification.
   D. Click Custom properties.
   E. If applicable, note the location of the LpidToGupidMapping.properties file.
   F. If the LpidToGupidMapping.properties file exists on the primary node, copy the file to the same location on the secondary node.

**Port fileNote:** Sample port files are available on the Setup disc.

```bash
./ConfigEngine.sh modify-ports-by-portsfile -DWasPassword=password -DModifyPortsServer=servername -DPortsFile=full path to ports file
```

The following is an example of the information within a port file although the port values will be different based on your environment:

```
BOOTSTRAP_ADDRESS=10031
SOAP_CONNECTOR_ADDRESS=10033
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=10032
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=10025
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=10036
WC_adminhost=10027
WC_defaulthost=33344
DCS_UNICAST_ADDRESS=10029
WCadminhost_secure=10039
WCdefaulthost_secure=10035
SIB_ENDPOINT_ADDRESS=10026
SIB_ENDPOINT_SECURE_ADDRESS=10037
SIB_MQ_ENDPOINT_ADDRESS=10030
SIB_MQ_ENDPOINT_SECURE_ADDRESS=10028
ORB_LISTENER_ADDRESS=10034
```

**Parent topic:** Preparing additional nodes on AIX

**Next topic:** Choosing the type of additional node to create on AIX

**Related concepts**

- Installation methods
- IBM Support Assistant Lite for WebSphere Portal

**Related reference**

- Advanced installation parameters
Choosing the type of additional node to create on AIX

If you created a static cluster using the IBM® WebSphere® Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

Choose one of the following options to add additional nodes to your cluster:

- **Adding additional nodes to the static cluster on AIX**
  After installing IBM WebSphere Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

- **Adding an additional node to an existing dynamic cluster**
  After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM WebSphere Virtual Enterprise dynamic cluster.

Parent topic: Preparing additional nodes on AIX

Previous topic: Installing WebSphere Portal on AIX on the additional nodes

Next topic: Choosing the type of vertical cluster to create on AIX
Adding additional nodes to the static cluster on AIX

After installing IBM® WebSphere® Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

Perform the following steps to add the secondary node to the cluster:

1. Perform the following steps on the secondary node to access your database server: **Note**: All properties files are located in the `{wp_profile_root}/ConfigEngine/properties` directory.
   
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users**: When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   
   C. Set all database properties in the `{wkplc_dbtype.properties}` and `{wkplc_comp.properties}` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   
   A. `./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password`
   
   B. `./ConfigEngine.sh validate-database-connection -DWasPassword=password -DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `{wkplc.properties}` file, located in the `{wp_profile_root}/ConfigEngine\properties` directory of the secondary node: **Note**: Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   
   A. Verify that `WasUserid` is set to your deployment manager administrator ID.
   
   B. Verify that `WasPassword` is set to your deployment manager administrator password.
   
   C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   
   D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   
   E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   
   F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is 8879.
   
   G. Verify that `PrimaryNode` is set to `false`.
   
   H. Verify that `ClusterName` is set to the primary node’s `ClusterName`.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `{wp_profile_root}/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
   
   **Note**: You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension database. (`la.DbType` is not set for a property extension database in the `{wkplc.properties}` file).
   
   A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `{wkplc.properties}` file.
   
   **Note**: If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is...
in the wkplc.properties file on the primary node.

B. Run the .\ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password - DDdDomain=ls|federated.db -DVmmNodeName=node_name -Ddb_type.NodeDbLibrary=local full path of the database jars task from the wp_profile_root/ConfigEngine directory to create the variable used to access the VMM database jars.

**Note:** VmmNodeName is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The db_type in db_type.NodeDbLibrary should be set to the type of database you are using, for example db2.

6. Run the .\ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the ServerName parameter in the wkplc.properties file after running the cluster-node-config-post-federation task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the .\ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password - DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task, from the wp_profile_root/ConfigEngine directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for -DWasPassword is the Deployment Manager administrative password.

**Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.

**Fast path:** If the value for newAdminGroupId contains a space; for example Software Group, open the wkplc.properties file and add the values for newAdminId, newAdminPw, and newAdminGroupId. Save your changes and run the ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password task.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the wp-change-portal-admin-user task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the wp-change-portal-admin-user task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the wp-change-portal-admin-user task. -DnewAdminPw is an optional parameter to update the Administrative password in the wkplc.properties file if required.

8. Optional: Open the wkplc.properties file and change the ServerName parameter from the default WebSphere_Portal_node_value to a value that meets your business needs. Do not change the parameter to WebSphere_Portal as this is the primary node value.

9. Run the .\ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password task to add the node to your cluster.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.

B. Select Environment > WebSphere Variables.

C. From the Scope drop-down menu, select the Node-node_name, Server-servername option to narrow the scope of the listed variables, where Node-node_name is the node that contains the application server.
D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

12. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Choosing the type of additional node to create on AIX

**Related tasks**

Deleting passwords from properties files
Adding an additional node to an existing dynamic cluster

After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM® WebSphere® Virtual Enterprise dynamic cluster.

On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

**Prerequisites**

- PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
- Installing and configuring the product:
  - Augmenting profiles
  - PK97393

Perform the following steps to add an additional node to an existing WebSphere Virtual Enterprise dynamic cluster:

1. Perform the following steps on the secondary node to access your database server. **Note**: All properties files are located in the `wp_profile_root/ConfigEngine/properties` directory.
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users**: When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   C. Set all database properties in the `wkplc_dbtype.properties` and `wkplc_comp.properties` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. `./ConfigEngine.sh validate-database-driver`  
      
      DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   
   B. `./ConfigEngine.sh validate-database-connection` -DWasPassword=password  
      
      DTransferDomainList=release,customization,community,jcr,feedback,likeminds

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root\ConfigEngine\properties` directory of the secondary node. **Note**: Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   A. Verify that `WasUserid` is set to your deployment manager administrator ID.
   B. Verify that `WasPassword` is set to your deployment manager administrator password.
   C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is `8879`.
   G. Verify that `PrimaryNode` is set to `false`.  

1273
H. Verify that **ClusterName** is set to the primary node’s **ClusterName**.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

   **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

   A. Set the property value for **federated.db.DbType** if using a database user registry or set the property value for **la.DbType** if using a property extension database in the `wkplc.properties` file.

      **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for **federated.db.DbType** to the same value that is in the `wkplc.properties` file on the primary node.

   B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

      **Note:** **VmmNodeName** is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The **db_type** in **Db_type.NodeDbLibrary** should be set to the type of database you are using, for example db2.

6. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the **ServerName** parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for **-DWasPassword** is the Deployment Manager administrative password. **Important:** You must provide the full distinguished name (DN) for the **newAdminId** and **newAdminGroupId** parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the **-Dskip.ldap.validation=true** parameter to the task to skip the validation.

   **Fast path:** If the value for **newAdminGroupId** contains a space; for example Software Group, open the `wkplc.properties` file and add the values for **newAdminId**, **newAdminPw**, and **newAdminGroupId**. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster)` task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. **-DnewAdminPw** is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Log on to the deployment manager administrative console.

9. Perform the following steps to add members to the node group:

   A. Click **System administration > Node groups**.
B. Click on the name of the node group that you want to add members to.
C. Click **Node group members** under Additional Properties.
D. Click **Add**.
E. Select the additional node you want to add into the node group and then click **Add**.
F. Click the **Save** link to save your changes to the master configuration.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Define or verify the following parameters in the **wkplc.properties** file, located in the **wp_profile_root**/ConfigEngine/properties directory:
   
   A. Set **ClusterName** to the name of the existing dynamic cluster.
   B. Verify that **CellName** is set to the deployment manager cell.
   C. Verify that **NodeName** is set to the local WebSphere Portal node.
   D. Set **ServerName** to the server that will be used for the dynamic cluster member on this node. **Note:** Log on to the deployment manager administrative console and click **Dynamic Clusters > PortalCluster > Dynamic cluster members** to find the name of the server used for the dynamic cluster.
   E. Verify that **PrimaryNode** is set to **false** because this is an additional node.

12. Run the **./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password** task to add the new member to the existing dynamic cluster. **Note:** This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

13. Perform the following steps to start the cluster member:
   
   A. Log on to the Deployment Manager administrative console.
   B. Navigate to **Servers > Dynamic clusters > cluster name > Dynamic cluster members**.
   C. Select the cluster member and click **Start**.
   D. Log off of the deployment manager administrative console.

14. Perform the following steps to access the Web Content Management content through an external Web server:
   
   A. Log on to the deployment manager administrative console.
   B. Select **Environment > WebSphere Variables**.
   C. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server.
   D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select **System Administration > Nodes**.
      2. Select the node that you want to synchronize from the list.
      3. Click **Full Resynchronize**.
   G. Log off of the deployment manager administrative console.

15. Run the following tasks to propagate your changes. **Note:** **WebSphere_Portal_nodename** is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the **serverstatus -all** task to get a list of the server names and their status.

   A. **./stopManager.sh -username admin_userid -password admin_password**, from the **dmgr_profile_root\bin** directory
   B. **./stopNode.sh -username admin_userid -password admin_password**, from the **wp_profile_root\bin** directory
   C. **./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password**
D. 
E. 
16. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

Choosing the type of vertical cluster to create on AIX

If you are using the IBM® WebSphere® Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

Choose one of the following options to add vertical cluster members to your cluster.

- **Adding vertical cluster members to a static cluster on AIX**
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

- **Adding vertical cluster members to a dynamic cluster on AIX**
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

**Parent topic:** Preparing additional nodes on AIX

**Previous topic:** Choosing the type of additional node to create on AIX
Adding vertical cluster members to a static cluster on AIX

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Log into the deployment manager administrative console.

2. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - For WebSphere Application Server Version 6.1: Click Servers > Clusters in the console navigation tree, select the cluster name, and then click Cluster members from the list of additional properties.
   - For WebSphere Application Server Version 7.0: Click Servers > Clusters > WebSphere application server clusters > cluster_name > Cluster members.

3. Click New to create the cluster member.
   A. Define the name of cluster member. **Note:** Do not use spaces in the cluster member name.
   B. Select an existing node where IBM® WebSphere® Portal is installed.
   C. Check the box Generate Unique HTTP Ports.
   D. Click Add Member and then click Next to view the summary.
      **Important:** You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.

4. Click Finish, and save the changes.

   - The new cluster topology can be viewed from the Servers > Cluster Topology view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the Servers > Clusters > Cluster Topology view.
   - The Servers > Application Servers view will list the new server cluster members. If using WebSphere Application Server Version 7.0, the Servers > Server Types > WebSphere application servers view will list the new server cluster members.

5. Perform the following steps to enable cache replication:
   A. From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new vertical cluster member(s).
   B. Click Dynamic cache service under Container services.
   C. Change Cache size to 3000 entries.
   D. Check the Enable cache replication check box.
   E. Select NOT_SHARED from the Replication type drop-down menu.
   F. Click OK.
   G. Click Save to save your changes to the master configuration.

6. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   A. Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   B. Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.
7. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click **Save** on the task bar, and save your administrative configuration.
   B. Select **System Administration > Nodes**, select the node from the list, and click **Full Resynchronize**.

8. Regenerate the Web server plug-in.
   A. Regenerate the Web server plug-in using the deployment manager administrative console.
   B. If you are using a remote Web server, copy the updated plug-in configuration file (**plugin-cfg.xml**) to the Web server's plug-in configuration directory.

9. Stop and start the Web server.

**Parent topic:** Choosing the type of vertical cluster to create on AIX
Adding vertical cluster members to a dynamic cluster on AIX

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Open a browser and enter http://DM01:9060/ibm/console in the address bar to access the administrative console on the deployment manager, where DM01 is the deployment manager node or host name. The port number might differ based on your installation.

2. Perform the following steps to allow vertical clusters on your dynamic cluster:
   - Navigate to Servers > Dynamic clusters and select the appropriate dynamic cluster.
   - Select the Allow more than one instance to start on the same node check box under Vertical stacking of Instances on node.
   - Enter a new value in the Number of instances text box to determine the number of vertical cluster members allowed on each node.
   - Click Apply and then click Save to save the changes to the master configuration.

   - The new cluster topology can be viewed from the Servers > Cluster Topology view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the Servers > Clusters > Cluster Topology view.
   - The Servers > Application Servers view will list the new server cluster members. If using WebSphere Application Server Version 7.0, the Servers > Server Types > WebSphere application servers view will list the new server cluster members.

   Important: You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.

3. Perform the following steps to enable cache replication:
   - From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new vertical cluster member(s).
   - Click Dynamic cache service under Container services.
   - Change Cache size to 3000 entries.
   - Check the Enable cache replication check box.
   - Select NOT_SHARED from the Replication type drop-down menu.
   - Click OK.
   - Click Save to save your changes to the master configuration.

4. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   - Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   - Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.

5. Save your changes and resynchronize the nodes.
   - In the administrative console for the deployment manager, click Save on the task bar, and save your administrative configuration.
B. Select **System Administration > Nodes**, select the node from the list, and click **Full Resynchronize**.

6. Stop and start the Web server.

**Parent topic:** Choosing the type of vertical cluster to create on AIX
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- Prerequisites
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX

Base Portal Tuning Scenarios

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services
Configuring search in a cluster on AIX

IBM® WebSphere® Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX
  - Tune your servers

- **Configuring Portal Search in a cluster on AIX**
  To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM WebSphere Application Server node that is not part of the IBM WebSphere Portal cluster.

- **Configuring JCR search in a cluster on AIX**
  To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

**Parent topic:** Setting up a cluster on AIX

**Previous topic:** Tune your servers

**Next topic:** Setting up multiple clusters on AIX
Configuring Portal Search in a cluster on AIX

To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM® WebSphere® Application Server node that is not part of the IBM WebSphere Portal cluster.

To install and configure the search service remotely, perform the following tasks:

1. Install and configure the search service to work remotely, that is, on a remote WebSphere Application Server node which is not part of the portal cluster. You can provide the remote search service either as an EJB or as a Web service via SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server node. For details about how to do this, refer to the WebSphere Application Server documentation.

2. Configure the search portlets for remote search service so that they access the remote server accordingly.

Notes:

1. If you have configured a remote search service for a portal cluster, you need to configure the default location for search collections to a directory on the remote server that has write access.

2. The portal site default search collection is created only once at the first time when an administrator selects the search administration portlet Manage Search. If this occurred before you configure the portlet for remote search, then the default portal site search collection is only available on the primary node of the cluster, but not on the remote server. In this case you need to recreate the portal site collection to make it available for search on all nodes of the cluster.

Parent topic: Configuring search in a cluster on AIX

Related concepts
Planning and preparing for Portal Search
Using remote search service

Related tasks
Configuring Portal Search for remote search service
Configuring the Search and Browse portlet for remote search service
Configuring the default location for search collections
Creating or resetting the portal site collection
Configuring the primary node to communicate with the deployment manager on AIX
Configuring the primary node to communicate with the deployment manager on HP-UX
Configuring a remote search service
Configuring JCR search in a cluster on AIX

To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization. Create a shared directory called `jcr/search` on a server in the network and ensure that each node in the cluster and the Deployment Manager has network access to the directory.

Note: If you are creating content in a clustered environment using the authoring portlet provided with Web Content Management, additional configuration steps are required to enable content created by these content features to be searchable in a cluster.

Perform the following steps on each server in the cluster to configure Search in a clustered environment:

1. Edit the `icm.properties` file, located in the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory.
2. Change the value of the `jcr.textsearch.indexdirectory` property to the shared directory; for example, `jcr.textsearch.indexdirectory=\\your_server\your_share\jcr\search`. You can specify the shared directory value in one of the following formats: Table 1. The format for the shared directory.

<table>
<thead>
<tr>
<th>Format</th>
<th>Shared directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal Naming Convention (UNC) format</td>
<td><code>\\your_server\your_share\jcr\search</code></td>
</tr>
<tr>
<td></td>
<td><code>\\hostname.example.com\share\jcr\search</code></td>
</tr>
<tr>
<td>Mounted resource format (with forward slashes)</td>
<td><code>/your_share/jcr/search</code></td>
</tr>
<tr>
<td></td>
<td><code>/mnt/jcr/search</code></td>
</tr>
<tr>
<td>Important:</td>
<td>This format requires that you mount the shared directory to the local server (for example, through a mapped network drive or a mounted directory). When using the mounted resource format, always use forward slashes instead of back slashes, regardless of the native operating system path format.</td>
</tr>
</tbody>
</table>

3. Required: Perform the following steps to delete the default search collections from the Manage Search portlet:

A. Log on to WebSphere Portal as an administrator.
B. Click Administration > Search Administration > Manage Search.
C. Click Search Collections.
D. Click the Delete Collection icon for the Portal Content search collection.
E. Click OK.
F. Restart the WebSphere Portal server.
G. Go to the Manage Search portlet and confirm that the Portal Content search collection was deleted.

Parent topic: Configuring search in a cluster on AIX
Setting up multiple clusters on AIX

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM® WebSphere® Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

Before attempting alternative approaches for building multiple portal-based clusters within a single cell, please contact IBM.

- Prerequisites
  - Preparing prerequisite and corequisite software on AIX
  - Preparing your AIX operating system
  - Preparing the primary node on AIX
  - Choosing the type of cluster to create on AIX
  - Tune your servers

1. Installing multiple clusters in a single cell on AIX

   Create a new, independent IBM WebSphere Portal cluster in a cell where a WebSphere Portal cluster already exists.

2. Routing requests across clusters on AIX

   The HTTP Server plug-in that comes with IBM WebSphere Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

Parent topic: Setting up a cluster on AIX

Previous topic: Configuring search in a cluster on AIX

Next topic: Sharing database domains between clusters on AIX
Installing multiple clusters in a single cell on AIX

Create a new, independent IBM® WebSphere® Portal cluster in a cell where a WebSphere Portal cluster already exists. In the following steps, Cluster A will be used to describe the existing cluster. Portal B will be used to describe the new server profile that will be the basis for the new cluster definition, Cluster B. Perform the following steps to install multiple clusters in a single cell:

1. Upgrade Cluster A, including the Deployment Manager node, to the current, supported hardware and software levels and to the current version of IBM WebSphere Portal.

2. Install and configure Portal B; see the "Preparing the primary node" topic for the appropriate operating system for details. **Important:** Maintain the same number of data sources with identical names to the Cluster A data sources so that data source bindings in the applications can be resolved on every cluster in which they run. If implementing database sharing across the clusters, the above statement refers to both the shared and non-shared domains; all domains should use the same names.

3. Optional: Using the same database user ID and password for each identically named domain/data source will allow the existing JAAS Authentication Aliases to be functional. If unique database user ID and password are required, additional manual configuration is needed to create new JAAS Authentication Aliases for each data source and map these accordingly. On the primary node of Cluster A, run the ./ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the new JAAS Authentication Aliases. where authDomainList is set to a list of domains which use unique database user ID and passwords and those domain properties are set correctly in the wkplc_comp.properties file, including user ID and password.

4. Optional: If necessary, upgrade Portal B to the current cumulative fix.

5. Run the ./ConfigEngine.sh mapped-app-list-create -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to build an inventory list of Portal B enterprise applications and portlets.

6. Stop the server1 and WebSphere_Portal servers on Portal B and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   - Set WasSoapPort to the deployment manager's port.
   - Set WasRemoteHostName to the full host name of the deployment manager.

7. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.

   **Important:** Ensure that you set WasUserId and WasPassword to the Deployment Manager user ID and password.

8. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=password task, from the wp_profile_root/ConfigEngine of the primary node.

9. Run the ./ConfigEngine.sh map-apps-to-server -DWasPassword=password task to determine which applications from the inventory list are no longer mapped to Portal B. The task uses the application profiles already in the cell to restore the mappings. Wait 30 minutes after running this task to allow all EAR files to expand before proceeding to the next step.

10. Perform the following steps to federate Portal B into the deployment manager cell:
    A. Ensure that all database parameters are correctly set, including passwords, in the wkplc_comp.properties and wkplc_dbtype.properties files.
B. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

C. After running the `cluster-node-config-post-federation` task, wait at least 30 minutes to allow all EAR files to expand.

D. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=waspassword -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

Important: If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

E. From the administrative console, click System Administration > Node Agents.

F. Check the box next to the required node agent and then click Restart.

G. Stop and restart the deployment manager.

H. Stop and restart the WebSphere_Portal server on Portal B

11. Restart the WebSphere_Portal server on Cluster A. Verify that Cluster A is functionally intact by spot checking pages and portlets and then verify that Portal B is functionally intact by spot checking pages and portlets that you deployed into Portal B before it was federated. Any discrepancies or errors should be corrected now before continuing. **Note:** If Portal B is using a non-default Portal server administrative ID, not wpsadmin, the server will not be functional until the cluster configuration is complete and the Portal administrative ID has been configured to match the Cells security settings.

12. Choose one of the following options to define a cluster using Portal B as the basis:
Perform the following steps to define a static cluster using Portal B as the basis:

1. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task.
2. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:
   - Configuring a Web server and an application server on separate machines (remote)
   - Configuring a Web server and an application server profile on the same machine
   - Configuring a Web server and a deployment manager profile on the same machine

   **Note:** Start with the step about launching the Plug-ins installation wizard.
3. Perform the following steps to access the Web Content Management content through an external Web server:
   - Log on to the deployment manager administrative console.
   - Select `Environment > WebSphere Variables`.
   - From the `Scope` drop-down menu, select the `Node=nodename, Server=servername` option to narrow the scope of the listed variables, where `Node=nodename` is the node that contains the application server.
   - Update the `WCM_HOST` variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   - Update the `WCM_PORT` variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   - Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere_Portal servers.
   - Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:
     - Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
     - Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Perform the following steps to define a dynamic cluster using Portal B as the basis:

1. Log on to the deployment manager administrative console.
2. Perform the following steps to create a node group:
   - Click **New**.
   - Type the node group **Name**.
   - Type any information about the node group in the **Description** text box.
   - Click **OK**.
   - Click the **Save** link to save your changes to the master configuration.
3. Perform the following steps to add members to the node group:
   - Click **System administration > Node groups**.
   - Click on the name of the node group that you want to add members to.
   - Click **Node group members** under **Additional Properties**.
   - Click **Add**.
   - Select the primary node and then click **Add**.
   - Click the **Save** link to save your changes to the master configuration.
4. Perform the following steps to create a dynamic cluster in the node group:
   - Click **Servers > Dynamic clusters**.
   - Click **New**.
   - Select WebSphere Application Server from the **Server Type** pull-down menu and then click **Next**.
   - Type the cluster name in the **Dynamic cluster name** text box and then click **Next**.
   - Type the same value that you provided for the **ClusterName** parameter in the **wkplc.properties** file of your primary node.
   - Remove all default membership policies and then click **Subexpression builder**.
   - Enter the following information in the Subexpression builder window:
     - Select **Logical operator** pull-down menu.
     - Select **Nodegroup** from the **Select operand** pull-down menu.
     - Select **Equals (=)** from the **Operator** pull-down menu.
     - Type the nodegroup name you created in the previous step in the **Value** text box.
   - Click **Generate subexpression**.
   - Click **Append**.
   - Click **Preview membership** to verify that all nodes included in the nodegroup display and then click **Next**.
   - Click the **Create the cluster member using an existing server as a template** radio button and then select the WebSphere Portal server for the primary node from the pull-down menu.
   - Click **Next**.
   - Specify the dynamic cluster properties and then click **Next**.
   - Review the summary page to verify your actions and then click **Finish**.

Define or verify the following parameters in the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory:

- **ClusterName** to the name of the new dynamic cluster.
- **CellName** is set to the deployment manager cell.
- **NodeName** is set to the local WebSphere Portal node.
- **ServerName** to the server that will be used for the dynamic cluster member on this node.
- **PrimaryNode** is set to true.

Run the 

```
./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password
```
task from

the **wp_profile_root/ConfigEngine directory** to create the dynamic cluster.
13. Install any additional nodes to the cell to support additional cluster members for **Cluster B** identically to the primary node, and then federate as them as secondary nodes and define as cluster members on these nodes. For information about adding additional nodes navigate to **Installing WebSphere Portal > Setting up WebSphere Portal > Setting up a clustered production environment**. Select the appropriate operating system and navigate to **Preparing additional nodes**. You can then choose to add an additional static or dynamic cluster and/or a vertical static or dynamic cluster.

14. Restart the server1 and WebSphere_Portal servers on **Cluster A** and **Cluster B**.

15. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

Installation of **Cluster B** is complete. It is now an independent cluster from **Cluster A**, which means that **Cluster B** can have its own configuration, set of end-user portlets, and target community. Any applications that are common between **Cluster A** and **Cluster B** are most likely infrastructure or related to administration, and special care needs to be taken to preserve their commonality between clusters and correct maintenance levels.

Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Routing requests across clusters on AIX

The HTTP Server plug-in that comes with IBM® WebSphere® Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

An important consideration in a multiple cluster environment is ensuring that all subsequent HTTP requests for an end user are routed to the same cluster that processed the first HTTP request. The WebSphere Portal login processing depends upon preserving this cluster affinity during this initial time until the user has successfully logged in and session cookies maintain affinity. In order to guarantee that affinity is preserved during login, set the Navigator Service public.session parameter to a value of true. Refer to “Portal Configuration Services” for information on how to configure this parameter.

Parent topic: Setting up multiple clusters on AIX
Previous topic: Installing multiple clusters in a single cell on AIX
Sharing database domains between clusters on AIX

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM® WebSphere® Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

**Prerequisites**
- Preparing prerequisite and corequisite software on AIX
- Preparing your AIX operating system
- Preparing the primary node on AIX
- Choosing the type of cluster to create on AIX
- Tune your servers

**Important:** JCR domains and release domains cannot be shared between different Web Content Management clusters or servers. Each distinct cluster or server in your Web Content Management system must use a separate JCR or release domain. For example:

<table>
<thead>
<tr>
<th>Development Server</th>
<th>Authoring Cluster</th>
<th>Staging Server</th>
<th>Delivery Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>JCR Domain 1</td>
<td>JCR Domain 2</td>
<td>JCR Domain 3</td>
<td>JCR Domain 4</td>
</tr>
<tr>
<td>Release Domain 1</td>
<td>Release Domain 2</td>
<td>Release Domain 3</td>
<td>Release Domain 4</td>
</tr>
</tbody>
</table>

Perform the following steps to share database domains when setting up an environment with multiple clusters:

1. Set up the first cluster (referred to as Cluster A in these instructions).
2. Determine which database domains you want to share with any other clusters in the environment.
3. Install the primary node of the next cluster (Cluster B), and perform the following steps to configure the node to use the shared database domains.
   A. Perform a partial database transfer of the database domains that you are not sharing. For example, if you are sharing only the Customization and Community domains, you would transfer the remaining domains to the database you are using for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.
4. Continue setting up the primary node as described in the cluster instructions.
5. Install the secondary node of Cluster B, and perform the following steps to configure the node to use the shared database domains.
   A. For those database domains that you are not sharing between clusters, reconfigure the domains to connect to the database domains you are using for Cluster B. As in the example for the primary node, if you are sharing only the Customization and Community domains, reconfigure the remaining domains on the secondary node to use the domains of the primary node for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to
those domains from Cluster B.

6. Continue setting up the secondary node as described in the cluster instructions.

**Related tasks**  
Connecting to existing database domains
Setting up a cluster on HP-UX

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

**Prerequisites**
- Technotes for installation and configuration issues

Perform the following tasks to set up your production environment on HP-UX:

1. **Preparing prerequisite and corequisite software on HP-UX**
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your HP-UX operating system**
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on HP-UX**
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Choosing the type of cluster to create on HP-UX**
   If you installed a IBM WebSphere Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

5. **Preparing a remote Web server when portal is installed on HP-UX**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment**
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

7. **Preparing additional nodes on HP-UX**
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

8. **Tune your servers**
   Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

9. **Configuring search in a cluster on HP-UX**
   IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.
10. Setting up multiple clusters on HP-UX

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

11. Sharing database domains between clusters on HP-UX

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

Parent topic: Setting up a cluster
Preparing prerequisite and corequisite software on HP-UX

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. Preparing the WebSphere Application Server Deployment Manager on HP-UX
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. Preparing a remote Web server when portal is installed on HP-UX
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

Parent topic: Setting up a cluster on HP-UX
Next topic: Preparing your HP-UX operating system
Preparing the WebSphere Application Server Deployment Manager on HP-UX

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command: `cd_root/HP-UX/architecture/ifpackage/WAS/install`, where `cd_root` is the root directory of the disc and `architecture` is the system's processor architecture.

2. Choose one of the following options to create a default deployment manager profile:

   **Important:** While creating the default deployment manager profile, enable administrative security. If you use the Profile Management Tool, check the enable administrative security check box. If you use the `manageprofile` command, add the `-enableAdminSecurity=true` parameter to the command line.

3. Run the following command to start the deployment manager: `./startManager.sh`, from the `dmgr_profile_root/bin` directory.

4. Use the following URL to launch the network deployment administrative console: `http://dmgr_hostname:9060/ibm/console`, where `dmgr_hostname` is the fully qualified host name for the WebSphere Application Server Network Deployment.

5. Log into the deployment manager administrative console.

6. Increase the HTTP connection timeouts for the deployment manager.

   A. Click **System Administration** > Deployment Manager > Web container transport chains.

   B. Increase the timeout values. For the `WCinboundAdmin` and `WCinboundAdminSecure` entries listed in the web container transport chains section, complete the following steps to increase the timeout values:

      1. Click **HTTP Inbound Channel**.
      2. Change the **Read timeout** value to 180.
      3. Change the **Write timeout** value to 180.
      4. Save the configuration changes.

7. Change the timeout request period for the Java Management Extensions (JMX) connector.

   A. Click **System administration** > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties.

   B. Select the `requestTimeout` property, and increase the value from 600 to 6000.

   C. Save the configuration changes.

8. Update the maximum Java heap size used by the deployment manager:

   A. Click **System administration** > Deployment manager > Java and Process Management > Process Definition > Java Virtual Machine.

---

<table>

</thead>
<tbody>
<tr>
<td>Profile Management Tool</td>
<td>See Creating a deployment manager profile for information.</td>
</tr>
<tr>
<td><code>manageprofile</code> commands</td>
<td>See manageprofile commands for information. <strong>Note:</strong> If you have a 64-bit</td>
</tr>
<tr>
<td></td>
<td>environment, only the manageprofiles command is supported when creating</td>
</tr>
<tr>
<td></td>
<td>profiles.</td>
</tr>
</tbody>
</table>

---

**Operating systems:** AIX, HP-UX, i5/OS, Linux, Solaris, Windows
B. Update the value in the **Maximum Heap Size** field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management *Product Documentation* page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.

C. Click **OK** and then save your changes.

9. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:

   **Note:** If security is not enabled on your deployment manager, see *Enabling security* for information before performing this step.

   - For **WebSphere Application Server Version 6.1**: Click **Security > Secure administration, applications and infrastructure** and select **Enable Application Security**. Then save the configuration changes.

   - For **WebSphere Application Server Version 7.0**: Click **Security > Global security** and select **Enable Application Security**. Then save the configuration changes.

10. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:

   A. Click **Users and Groups > Manage Users**.

   B. Click **Create**.

   C. Type the information for the WebSphere Portal administrative users; for example *wpsadmin* and *wpsbind*, and then click **Create**.

   D. Click **Users and Groups > Manage Groups**.

   E. Click **Create**.

   F. Type *wpsadmins* as the name of the WebSphere Portal administrative group and then click **Create**.

   G. Click the group you just created; for example *wpsadmins*.

   H. Click the **Members** tab.

   I. Click **Add Users**.

   J. Search for the users.

   K. Select the users you want to add to the group.

   L. Click **Add** to add the users to the group.

   M. Click **Close** when you are done adding users to the group.

   N. Log out of the administrative console.

11. Change the timeout request period for the Simple Object Access Protocol (SOAP) client. Edit the *soap.client.props* file, located in the *Dmgr_profile/properties* directory: Change the line to: `com.ibm.SOAP.requestTimeout=6000`.

12. Run the following tasks to stop and restart the deployment manager:

   A. `. /stopManager.sh -username admin_userid -password admin_password`, from the *dmgr_profile_root/bin* directory

   B. `. /startManager.sh`, from the *dmgr_profile_root/bin* directory

**Parent topic:** Preparing prerequisite and corequisite software on HP-UX

**Next topic:** Preparing a remote Web server when portal is installed on HP-UX
Preparing a remote Web server when portal is installed on HP-UX

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on HP-UX
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.

2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.

3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `On`; the directive should be added at the root level as a global directive.

4. Stop the Web server.

5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to the Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

   **If using WebDAV:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

   **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.

7. Start the Web server.
Preparing your HP-UX operating system

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- Prerequisites
  - Preparing prerequisite and corequisite software on HP-UX

Configuring HP-UX kernel settings before installing

To set kernel parameters, perform the following steps:

1. Log into the host machine with superuser (root) privileges.
2. Choose one of the following options to determine the physical memory, which you must know to avoid setting certain kernel parameters above the physical capacity:
   - HP-UX 11i Version 3 and later: Use the /usr/sbin/dmesg command.
   - HP-UX 11i Version 2 and earlier: Perform the following steps:
     A. Start the HP-UX System Administration Manager (SAM) utility with the /usr/sbin/sam command.
     B. Select Performance Monitors > System Properties > Memory.
     C. View the value for Physical Memory and click OK.
     D. Exit from the SAM utility.
3. Set the maxfiles and maxfiles_lim parameters to at least 4096. (The table below recommends 8000 and 8196, respectively. You must first edit the /usr/conf/master.d/core-hpux file, to allow the SAM utility to set values greater than 2048: Note; If using HP-UX 11i Version 2, the /usr/conf/master.d/core-hpux file does not exist; instead, use the SAM utility to set the new kernel parameter values. See Reconfiguring the Kernel (HP-UX 11i Version 2) for details.
   A. Open the file /usr/conf/master.d/core-hpux in a text editor.
   B. Change the line, "*range maxfiles<=2048" to "*range maxfiles<=60000"
   C. Change the line, "*range maxfiles_lim<=2048" to "*range maxfiles_lim<=60000"
   D. Save and close the file. Old values might be stored in the /var/sam/boot.config file. Force the SAM utility to create a new boot.config file:
      1. Move the existing version of the /var/sam/boot.config file to another location, such as the /tmp directory.
      2. Start the SAM utility.
      3. Select Kernel Configuration > Configurable Parameters. When the Kernel Configuration window opens, a new boot.config file exists. Alternatively, rebuild the boot.config file with this command: #
         /usr/sam/lbin/getkinfo -b
4. Web Content Management only: Use the ulimit -f command to set the maximum size of files that can be created to be at least the size of the largest file you would need to upload to the content server. The command ulimit -f -1 removes any limit on file size.
5. Set new kernel parameter values:
   A. Start the SAM utility.
   B. Select Kernel Configuration > Configurable Parameters.
   C. For each of the parameters in the following table, perform this procedure:
      1. Highlight the parameter to change.
      2. Select Actions > Modify Configurable Parameter.
      3. Type the new value in the Formula/Value field.
4. Click OK.

**Note:** When WebSphere Portal and DB2 are installed on the same machine, some kernel values are higher than those shown in the table below. If you are using this configuration, refer to the following site for more information:

Typical kernel settings for running WebSphere Portal appear in the following table: *Table 1. The typical kernel settings for running WebSphere Portal*

<table>
<thead>
<tr>

**Parent topic:** Setting up a cluster on HP-UX  
**Previous topic:** Preparing prerequisite and corequisite software on HP-UX  
**Next topic:** Preparing the primary node on HP-UX
Preparing the primary node on HP-UX

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system

Perform the following tasks to prepare your primary node:

1. **Installing WebSphere Portal on HP-UX on the primary node**
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. **Configure WebSphere Portal to use a remote database**
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

3. **Configuring the primary node to communicate with the deployment manager on HP-UX**
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. **Removing search collections on HP-UX**
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Parent topic:** Setting up a cluster on HP-UX  
**Previous topic:** Preparing your HP-UX operating system  
**Next topic:** Choosing the type of cluster to create on HP-UX
Installing WebSphere Portal on HP-UX on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method.

Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - Application Server
   - Administration
   - Scripted Administration
   - Administrative Console
   - Ant and Deployment Tools
   - Deploy Tool
   - Ant Utilities

   **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.

   **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

4. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:

   **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.

   A. Install the current supported version of WebSphere Application Server as a root user.
   B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:

   1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.

   2. Run the following tasks to change the rights of the non-root user:

   ```
   chgrp -R group_name/opt/IBM
   chmod -R g+rw /opt/IBM
   chmod -R g+wr /tmp
   ```
chgrp -R group_name /tmp
chmod -R g+wr /var/tmp
chgrp -R group_name /var/tmp

C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

**Advance Installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

**Restriction:** When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \\, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Table 1. Installation task options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Installation type</strong></td>
</tr>
<tr>
<td>-----------------------</td>
</tr>
<tr>
<td><strong>Graphical user interface</strong></td>
</tr>
<tr>
<td><strong>Console mode</strong></td>
</tr>
<tr>
<td><strong>Silent install</strong></td>
</tr>
</tbody>
</table>

**Note:** If the installation program does not detect a WebSphere Application Server instance that you know exists, exit the installation program and pass the WebSphere Application Server instance location using the command line; for example, `./install.sh -W was.undetectedWas="/my/WAS/location"`.

**Note:** If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

6. Verify your installation was successful; access WebSphere Portal using the `http://yourserver:yourport/wps/portal` format. Run the `./ConfigEngine.sh list-server-ports -DWasPassword=passwort` task from the `wp_profile_root/ConfigEngine` directory to generate the `wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt` file that lists WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the `./ConfigEngine.sh configure-express -DPortalAdminPwd=your_password -DWasPassword=your_password` task, from the `wp_profile_root/ConfigEngine` directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

**Restriction:** Run the `configure-express` task before configuring your database, user registry, context root, security, etc. If you run any tasks other than the install task, do not run this task.

**Note:** See [http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html](http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html) for tutorials on how to use the sample content.

The sample content includes:

- Creates a group called contentAuthors; members of this group are given privileges to create content in the sample...
Internet and intranet sites. Navigate to the Administration area and then click Access > Users and Groups.
- Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0". Navigate to the Administration area and then click Portal Content > Web Content Libraries.
- Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the Environment area.
- Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to Theme Customizer and then select the style.
- Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.
- Creates two virtual portals with context roots of wps/portal/intranet and wps/portal/internet. These are the sample Internet and intranet sites. Go to http://yourserver:yourport/wps/portal/internet and http://yourserver:yourport/wps/portal/intranet to access them.
- Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the Administration area and then click Access > Credential Vault > Manage System Vault Slots.
- Modifies the portlet palette to include some new portlets. Click the Portlets link to see the portlet palette.

8. Optional: If you ran the configure-express task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as uid=xyzadmin,o=defaultWIMFileBasedRealm. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:
   A. Edit the wp_profile_root /PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.
   B. Add the following line to the file:
      
      uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

      Replace portal_admin_DN with the distinguished name of the portal administrator.
   C. Save your changes and close the file.
   D. Run the ./ConfigEngine.sh action-express-memberfixer -DPortalAdminPwd=password -DWasPassword=password task, located in the wp_profile_root/ConfigEngine directory.

9. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

   **Note:** The starting port parameter is required for a successful completion of the modify-ports-by-startport task.

   Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

   A. Stop the server1 and WebSphere_Portal servers.
   B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

10. To prevent Out of Memory errors, perform the following steps to set the **MaxPermSize**: Tip: If **Maximum Heap Size** is set to 2048 M or higher, set the **MaxPermSize** to a quarter of the value entered for the **Maximum Heap Size**; for example, if your **Maximum Heap Size** is 3000 M, set **MaxPermSize** to 750 M. If your **Maximum Heap Size** is less than 2048 M, set **MaxPermSize** to 512 M.

A. Log in to the WebSphere Application Server Administration Console.

B. Click **Servers > Server Types > WebSphere application servers > WebSphere_Portal**.

D. In the **Generic JVM arguments** field, change the **MaxPermSize** value to `-XX:MaxPermSize=numeric value`, where `numeric value` is a quarter of the value entered for the **Maximum Heap Size**.

Important: **MaxPermSize** does not exist in the **Generic JVM arguments** field, add it to the field but do not replace existing information in the **Generic JVM arguments** field with the **MaxPermSize** information.

E. Click **OK** to save your changes.

F. Click **Save** to save your changes to the master configuration.

G. Log out of the WebSphere Application Server Administration Console.

H. Restart the server1 and WebSphere_Portal servers.

**Port file**

**Note:** Sample port files are available on the Setup disc.

```bash
./ConfigEngine.sh modify-ports-by-portsfile -
DWasPassword=password -
DModifyPortsServer=servername -
DPortsFile=full path to ports file
```

The following is an example of the information within a port file although the port values will be different based on your environment:

- `BOOTSTRAP_ADDRESS=10031`
- `SOAP_CONNECTOR_ADDRESS=10031`
- `SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=10032`
- `CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=10025`
- `CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=10036`
- `WC_adminhost=10027`
- `WC_defaulthost=33344`
- `DCS_UNICAST_ADDRESS=10029`
- `WC_adminhost_secure=10039`
- `WC_defaulthost_secure=10035`
- `SIB_ENDPOINT_ADDRESS=10026`
- `SIB_ENDPOINT_SECURE_ADDRESS=10037`
- `SIB_MQ_ENDPOINT_ADDRESS=10030`
- `SIB_MQ_ENDPOINT_SECURE_ADDRESS=10028`
- `ORB_LISTENER_ADDRESS=10034`

Advanced installation parameters
Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

Password considerations when transferring data manually

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts.

Alternatively, you can specify the password on the command line using the following syntax:

- Windows: ConfigEngine.bat task_name -Dpassword_property_key=password_value
- UNIX: ./ConfigEngine.sh task_name -Dpassword_property_key=password_value
- i5/OS: ConfigEngine.sh task_name -Dpassword_property_key=password_value

As with other properties, each password property must have the -D prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each -Dproperty=value setting.

- Prerequisites
  - Installing WebSphere Portal on HP-UX on the primary node
  - ▶ Technotes for database connectivity issues

- Configuring WebSphere Portal to use DB2
  View information on installing and setting up DB2 to work with WebSphere Portal.

- Configuring WebSphere Portal to use DB2 for z/OS
  View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle
  View information on installing and setting up Oracle to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle RAC
  View information on installing and setting up Oracle RAC to work with WebSphere Portal.

- Configuring WebSphere Portal to use SQL Server
  View information on installing and setting up SQL Server to work with WebSphere Portal.

- Verifying databases
  After you configure IBM WebSphere Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.
Troubleshooting WebSphere Portal Version 6.1 databases
Configuring WebSphere Portal to use DB2

View information on installing and setting up DB2 to work with WebSphere Portal.

1. **Installing DB2**
   View information on installing DB2 for use with WebSphere Portal.

2. **Create users**
   View the steps to set up users for DB2 to work with WebSphere Portal.

3. **Creating remote databases**
   A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

4. **Optional: Assigning custom table spaces**
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

5. **Modifying database properties**
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

6. **Optional: Configuring JCR collation support**
   View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

7. **Configure WebSphere Portal to use DB2**
   View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

8. **Configuring DB2 for large file handling in Web Content Management**
   If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

9. **Optional: Changing driver types**
   WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing DB2

View information on installing DB2 for use with WebSphere Portal.

Before you begin:

- Make sure DB2 is set up with updated kernel parameters according to the recommendations in the DB2 Quick Beginnings guide at DB2 Technical Support.

- **(For Type 2 drivers only):** DB2 Connect must be installed on the same system as WebSphere Portal, and have the same name as the server profile name.

- When you install DB2 using the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.

1. If you are using the JDBC driver in type 2 mode, configure your DB2 Connect client with the following commands. If you are using a remote database, complete this step separately from the WebSphere Portal installation.
   - `db2 update dbm cfg using tp_mon_name WAS`
   - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name of WebSphere Portal.

   Because the default for `spm_name` is the hostname itself, specifying the `hostname` parameter is optional. If your hostname is more than eight characters, use empty double quotes (" "). For example, `db2 update dbm cfg using spm_name " "`.

2. Before installing DB2, log in with a user ID that has administrative authority.

3. To install DB2, follow the instructions that are provided with the DB2 documentation to install DB2 and the required fix pack.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Next topic:** Create users

**Related Information**

- [DB2 Technical Support](#)
- [DB2 Information Center](#)
Create users

View the steps to set up users for DB2 to work with WebSphere Portal.

Before you begin: You should have completed Installing DB2.

**Prerequisites**

- Installing DB2

For all databases, use one user with administrative rights on the operating system and the DB2 installation. This user can be the database administrative user that is created automatically by the DB2 installation program. This user is the database configuration user that will be used for configuration tasks: creating database tables and performing database transfer. If you choose to have WebSphere Portal also create the databases, the database user should be given SYSADM rights. You only need to manually create an administrator ID when you do not want to use an existing DB2 administrator ID.

A common user name is **db2inst1**, but you can assign any user name as long as it has administrative access and follows the limitations listed here. Do not change the user name after creating it.

The limitations on user names are:

- User names can contain one to eight characters.
- Group and instance names can contain one to eight characters.
- Names cannot be any of the following: **users**
  - **admins**
  - **guests**
  - **public**
  - **local**
- Names cannot begin with: **IBM**
  - **SQL**
  - **SYS**
- Names cannot include accented characters.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Following are the basic steps to create new users and grant privileges. For more information, refer to the DB2 product documentation.

1. From the DB2 Control Center, expand the object tree until you find the DB Users folder.
2. Right-click the DB Users folder and select **Create/Add**. The Create DB User notebook opens.
3. In the User name field, type a user ID.
4. Assign an authority for the user.
5. Click **OK**.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Installing DB2

**Next topic:** Creating remote databases
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before creating these databases, note the following information:

- Use IBM® DB2 Universal Database™ Enterprise Server Edition JDBC driver, JCC, type 4.
- If the DB2 JDBC type 4 driver is used, only the instructions on the remote server are required. You do not need to install the DB2 client software, and you do not need to complete the steps related to the DB2 client.
- The client software, DB2 Connect, must be correctly configured to connect to the remote DB2 server instance, for example, db2inst1.
- These instructions assume that a remote DB2 server and DB2 Connect are already installed and running. For information on installing DB2 Connect, see the DB2 product documentation.

**Prerequisites**

- Installing DB2
- Create users

To create a database, you must be a DB2 System Administrator with sufficient database privileges (SYSADM or at a minimum SYSCtrl).

1. Log in to the DB2 server system as a user with sufficient database privileges.
2. Initialize a DB2 command environment by opening a command prompt and typing `su - db2inst1`, where `db2inst1` is the database user. The prompt changes to your operating system shell prompt, for example: `$.` In this mode, you must type `db2` at the beginning of each command and use double quotation marks (""") around the entire command. The following example shows how to use the double quotes; it is not an actual command that you run:

   ```
   db2 "CREATE REGULAR TABLESPACE SMS PAGESIZE 4 K MANAGED BY SYSTEM USING ('sms') BUFFERPOOL SMSPOOL"
   ``

   **Note:** If you are using the Command Line Processor (CLP), refer to your DB2 documentation for details. The command prompt is `db2=>`. In this mode, commands can be entered without the `db2` prefix or the double quotation marks. However, the following steps assume you are not using the CLP and are entering commands from your operating system shell prompt, for example: `$.`

3. Run the following commands on the DB2 server system to configure the DB2 database instance:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>db2set DB2_RA_TO_RS=YES db2set DB2_EVALUNCOMMITTED=YES db2set DB2_INLIST_TO_NLJN=YES db2 &quot;UPDATE DBM CFG USING query_heap_sz 32768&quot; db2 &quot;UPDATE DBM CFG USING maxagents 500&quot; db2 &quot;UPDATE DBM CFG USING sheapthres 0&quot;</td>
</tr>
</tbody>
</table>

4. **(Important)** Failure to complete this step will result in an unsuccessful database transfer. Run the following commands on the DB2 server system to create the necessary databases. **Notes:**

   - Replace `dbname` with the actual name of the database. Run the commands and each time replace `dbname` with the actual values for release, community, customization, Java Content Repository, Feedback, and Likeminds. You will need to run the commands once for each database for a total of six times. **Remember:** DB2 database names cannot...
5. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (jcrdb).

- jcrdb is the name of the database used to store user data and objects
- jcr is the jcr user for jcrdb
- dbpassword is the password for the jcr user for the jcrdb

```
db2 "CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192"
```

```
db2 "UPDATE DB CFG FOR dbname USING applheapsz 4096"
```

```
db2 "UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024"
```

```
db2 "UPDATE DB CFG FOR dbname USING stathheapsz 32768"
```

```
db2 "UPDATE DB CFG FOR dbname USING dbheap 2400"
```

```
db2 "UPDATE DB CFG FOR dbname USING locklist 1000"
```

```
db2 "UPDATE DB CFG FOR dbname USING logfilsiz 4000"
```

```
db2 "UPDATE DB CFG FOR dbname USING logprimary 12"
```

```
db2 "UPDATE DB CFG FOR dbname USING logsecond 20"
```

```
db2 "UPDATE DB CFG FOR dbname USING logbufsz 32"
```

```
db2 "UPDATE DB CFG FOR dbname USING avg_appls 5"
```

```
db2 "UPDATE DB CFG FOR dbname using AUTO_MAINT off"
```

5. Complete the following:

A. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (jcrdb).

- jcrdb is the name of the database used to store user data and objects
- jcr is the jcr user for jcrdb
- dbpassword is the password for the jcr user for the jcrdb

```
db2 "CONNECT TO jcrdb USER jcr USING dbpassword"
```

```
db2 "CREATE BUFFERPOOL ICMLSFREQBP4 SIZE 1000 PAGESIZE 4 K"
```

```
db2 "CREATE BUFFERPOOL ICMLSVOLATILEBP4 SIZE 16000 PAGESIZE 4 K"
```

```
db2 "CREATE BUFFERPOOL ICMLSMAINBP32 SIZE 16000 PAGESIZE 32 K"
```

```
db2 "CREATE BUFFERPOOL CMBMAIN4 SIZE 1000 PAGESIZE 4 K"
```

```
db2 "CREATE REGULAR TABLESPACE ICMLFQ32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLFQ32') BUFFERPOOL ICMLSMAINBP32"
```

```
db2 "CREATE REGULAR TABLESPACE ICMLNF32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLNF32') BUFFERPOOL ICMLSMAINBP32"
```

```
db2 "CREATE REGULAR TABLESPACE ICMVFPQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMVFPQ04') BUFFERPOOL ICMLSVOLATILEBP4"
```

```
db2 "CREATE REGULAR TABLESPACE ICMSFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMSFQ04') BUFFERPOOL ICMLSFREQBP4"
```

```
db2 "CREATE REGULAR TABLESPACE CMBINV04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('CMBINV04') BUFFERPOOL CMBMAIN4"
```

```
ds2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLSSYSTSPACE32') BUFFERPOOL ICMLSMAINBP32"
```

```
db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSSYSTSPACE4 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMLSSYSTSPACE4') BUFFERPOOL ICMLSVOLATILEBP4"
```

```
db2 "DISCONNECT jcrdb"
```

```
db2 "TERMINATE"
```

B. For JDBC Type 2 connections only: On DB2 Connect, use a text editor to open the /etc/services file. If it does not specify the DB2 connection service port, add the following text to specify the port for the remote DB2 instance:

```
db2c_<db2inst1>port1/tcp # DB2 connection service port
```

where <db2inst1> is the name of the DB2 instance ID on the system, and <port1> with the actual port number that is
assigned to the DB2 connection service in your DB2 server installation. The connection service port on the DB2
Client system, WebSphere Portal server, must match the connection service port on the DB2 server. The ports
should match by number but not necessarily by name.

C. Set up the correct service name by entering the following command on the DB2 server system: db2 "UPDATE DBM
CFG USING svcname svce_name" where svce_name is the connection service port name that is specified above.

D. For JDBC Type 2 connections only: On DB2 Connect, set DB2COMM to TCP/IP by using the db2set command
db2set DB2COMM=tcpip.

E. For JDBC Type 2 connections only: Catalog the TCP/IP node with the IP address of the remote database server on
DB2 Connect: db2 "catalog tcpip node remote_db_node_alias remote database_server_node server
collection_service_port" where:
- remote_db_node_alias is the alias name of the database server that you are defining for the WebSphere Application
  Server node name. The alias name can contain one to eight characters.
- database_server_node is the fully qualified host name of your database server system.
- connection_service_port is the name of the DB2 connection service port that is configured in the /etc/services
  file on the database server system.

F. For JDBC Type 2 connections only, catalog the WebSphere Portal databases on DB2 Connect, where:
- remote_db_name_domain, is the cataloged name of the databases on the server system for each domain.
- domain_alias_name, is the database alias names that you are defining.
- remote_db_node_alias is the name that was used previously when you cataloged the TCP/IP node in the previous
  step.

The alias for each database must be different from the actual database name and can only contain up to eight
characters.db2 "catalog db remote_db_name_release as release_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_community as comm_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_customization as cust_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_fdbkdb as fdbkdb_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_lmdb as lmdb_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_jcrdb as jcrdb_alias_name at node remote_db_node_alias"

G. For JDBC Type 2 connections only: Log out of DB2 Connect by entering db2 "terminate".

H. For JDBC Type 2 connections only, on DB2 Connect, test your remote connection by issuing the following command
in the DB2 command window: db2 "connect to alias_name user username using password", where alias_name
is the alias name that you defined above, username is the database user, and password is the password assigned to
the database user.

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Create users
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the \wp_profile_root\PortalServer/config/tablespaces/ddomain.space_mapping.properties file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file \wp_profile_root\PortalServer/config/tablespaces/ddomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - ddomain.table_name.tablespace
   - ddomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, ddomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword IN and a space. For example: community.COMP_INST.tablespace=IN COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close ddomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
   - UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Creating remote databases  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and Like Minds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:

  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custdb

  - If you are using a remote database, enter the values for the remote server.
  - Use a forward slash (/) instead of a backslash (\).
  - There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
  - The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
  - Depending on which database domain has to be configured, replace dbdomain with:
    - release
    - customization
    - community
    - jcr
    - feedback
    - likeminds

  - The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
- `dbname DbType`
- `dbname DbName`
- `dbname DbUrl`
- `dbname DbSchema`

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wprofile_root/ConfigEngine/properties/wkplc.properties`
   - `wprofile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wprofile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   A. For `dbname DbType`, type `db2`.
   B. For `dbname DbName`, type the name of the WebSphere Portal domain database. **Notes:**
      - This value is also the database element in the `dbname DbUrl` property.
      - This value is the TCP-IP alias for the database.
   C. For `dbname DbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For `dbname DataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For `dbname DbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of `DbName`.
   F. For `dbname DbUser`, type the user ID for the database administrator.
   G. For `dbname DbPassword`, type the password for the database administrator.
   H. Optional: For `dbname DbRuntimeUser`, type the user ID of the database user that should be used by WebSphere Portal to connect to the database at runtime.
   I. If `dbname DbRuntimeUser` is specified, you must set `dbname DbRuntimePassword` to be the password of the runtime database user.
   J. For `dbname DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.
K. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.
L. For `dbdomain.XDbName`, type the database loop back alias that needs to be set if you plan to use the `create-database` task. **Note:** Required only for local databases using a JDBC Type 2 driver.
M. For `dbdomain.DbNode`, type the value for the node database. Set this value if you want to call `create-database`. **Note:** Required only for local databases.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domain DbType`, type of the database you are currently configured to use. The value for `source.domain DbType` is Derby by default.
B. For `source.domain DbName`, type the name of the database domain you are currently using.
C. For `source.domain DbSchema`, type current schema identifier for objects within the database for this domain.
D. For `source.domain DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For `source.domain DbUrl`, type the url currently used to access your database.
F. For `source.domain DbUser`, type the name of the user accessing this database.
G. For `source.domain DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

A. For `db2.DbDriver`, type the name of the JDBC driver class.
B. For `db2.DbLibrary`, type the directory and name of the `.zip` or `.jar` file that contains the JDBC driver class.
C. For `db2.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Assigning custom table spaces  
**Next topic:** Configuring JCR collation support
Configuring JCR collation support

View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

1. Stop the WebSphere Portal server:
   ```
   ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```

2. If using a remote DB2 server, copy the following files from the WebSphere Portal server to a temporary directory on the remote DB2 server:
   ```
   PortalServer_root/jcr/prereq.jcr/config/collation.jar
   PortalServer_root/jcr/prereq.jcr/config/registerCollationUDFTemplate.sql
   ```

3. Set up collation on the database where the JCR domain is located.
   - Change to the directory `db2_instance_owner_home`/sqlib/function.
     ```
     Remote DB2:
     db2_instance_owner_home/sqlib/java/jdk/bin/jar -xvf temporary location/collation.jar icm/CollationUDF.class
     ```
     ```
     Local DB2:
     db2_instance_owner_home/sqlib/java/jdk/bin/jar -xvf PortalServer_root /jcr/prereq.jcr/config/collation.jar icm/CollationUDF.class
     ```
   - If using a local DB2, change to the directory `wp_profile_root`PortalServer/jcr/config. If using a remote DB2, change to the temporary directory where you copied the files in a previous step.

4. Open the file `registerCollationUDFTemplate.sql` and change all `SCHEMA` references to the JCR schema; for example, `JCR`. The value set for `SCHEMA` should match the value set for the `jcr.DbSchema` property. You specify `jcr.DbSchema` in the configuration file `wkplc_comp.properties` when you modify database properties.

5. Connect to the JCR database by running `db2 connect to <jcrdb> user <userid> using <password>`. You must connect to the JCR database using the userid and password of the WebSphere Portal JCR data source.

6. Execute the command `values schema.sortkeyj('abc','en')` in the previous step. If the command completes successfully, the UDF is registered correctly as follows:

7. Edit the `icm.properties` file, located in `wp_profile_root`PortalServer/jcr/lib/com/ibm/icm directory. Add the following section to the end of the file:

```
# Enable/Disable collation support for all DB2 platforms
```

---

**Operating systems:** AIX, HP-UX, i5/OS, Linux, Solaris, Windows
# Disabled by default
jcr.query.collation.db2.enabled = true

# Database specific collation mappings
# These mappings apply a Java locale name into a collation name
# supported by the underlying database.
# Example mappings for DB2 platform

# English
jcr.query.collation.en = en

# Swedish
jcr.query.collation.sv = sv

jcr.query.collation.zh = zh
jcr.query.collation.de = de
jcr.query.collation.da = da
jcr.query.collation.hu = hu
jcr.query.collation.jp = jp

6. Enter the following command to start the WebSphere Portal server:

   . /startServer.sh WebSphere_Portal

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Modifying database properties  
**Next topic:** Configure WebSphere Portal to use DB2
Configure WebSphere Portal to use DB2

View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

Tips:

- To run these tasks as a non-root user, you must first run the task chown -R non-root_user WebSphereDir.
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.
   A. Locate the file /home/db2inst1/sqllib/cfg/db2cli.ini.
   B. Add the following to the end of the file. Leave an empty line after ReturnAliases=0.[COMMON]
      
      [COMMON]
      DYNAMIC=1
      ReturnAliases=0

2. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.

3. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2. .

   /home/db2inst1/sqllib/db2profile
   where db2inst1 represents your database instance

   Note: You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

4. Enter the following commands to validate configuration properties...

   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password

   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password

5. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
6. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

7. Transfer the database:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.

   B. Enter the following command: `./ConfigEngine.sh database-transfer -DWasPassword=password`

   **Note:**
   - To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: `./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password`
   - If you have been storing data in IBM® Derby for a long time, database transfer could fail with OutOfMemory exceptions. If database transfer fails, add the following property to the command in this step: `./ConfigEngine.sh database-transfer -DDbtJavaMaxMemory=1536M -DWasPassword=password`

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.
   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

8. After transferring the database tables, perform a reorg check to improve performance. Perform this step for each database alias in the property file.

A. Connect to a database with the following command: `db2 connect to database_alias user db2admin_userid using password`

   **Note:** Additional options might be required if additional security has been installed. Refer to DB2 Universal Database commands by example for links to the command reference.

B. After it is connected, run the following commands from the DB2 prompt: `db2 reorgchk update statistics on table all > xyz.out`

C. Look in the reorg column for entries marked with a * (star or asterisk) in the file `xyz.out`. For each line with a *, note the `tablename` and run the following command for each `tablename`: `db2 reorg table tablename db2 terminate db2rbind database_name -l db2rbind.out -u db2_admin -p password`

D. The output file `db2rbind.out` is only created when there is an error for the `db2rbind` command.

9. Change to the directory `wp_profile_root/bin`.

10. Enter the following command to start the WebSphere Portal server: `./startServer.sh WebSphere_Portal`
Configuring DB2 for large file handling in Web Content Management

If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties
- Configure WebSphere Portal to use DB2

**Note:** You only need to perform these steps if you are using Web Content Management.

1. Log into the WebSphere Application Server administrative console.
2. Click **Resources > JDBC > Data sources**.
3. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
4. Select the name of the data source that is defined in `wkplc_comp.properties` for the JCR database domain. The default data source is `wpdbDS`.
5. Click **Custom properties**.
6. Ensure that the `fullyMaterializeLobData` property is set to `false`.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Configure WebSphere Portal to use DB2

**Next topic:** Changing driver types
Changing driver types

WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Before you begin, ensure that the following conditions are met:

- The WebSphere Portal database has been successfully transferred to DB2 using the `database-transfer` configuration task.
- The files `wkplc_comp.properties` and `wkplc_dbtype.properties` have been modified to set the correct values for the DB2 drivers that you are switching to:

  In the file `wkplc_comp.properties` set each `<Domain>.DbUrl` property using the following formats:
  
  ```
  # db2 (type 2):
  jdbc:db2:wpsdb
  
  # db2 (type 4):
  jdbc:db2://<YourDatabaseServer>:50000/wpsdb:returnAlias=0;
  ```

  In the file `wkplc_dbtype.properties` set the `db2.DbLibrary` property using the following format:

  ```
  # For DB2 Type 2
  <SQLLIB>/java/db2java.zip
  
  # For DB2 Type 4 driver use
  <SQLLIB>/java/db2jcc.jar:<SQLLIB>/java/db2jcc_license_cu.jar
  ```

  In the file `wkplc_dbtype.properties` set the `db2.DbDriver` property using the following format:

  ```
  # For DB2 Type 2
  COM.ibm.db2.jdbc.app.DB2Driver
  
  # For DB2 Type 4 driver use
  com.ibm.db2.jcc.DB2Driver
  ```

**Note:** If WebSphere Portal is installed on the same machine as the DB2 server and you switch from a JDBC Type 4 connection to a JDBC Type 2 connection, verify that you have created the alias names for the DB2 databases as described in `Creating remote databases` and that the alias names are specified for the databases in the file `wkplc_comp.properties`. When switching from a JDBC Type 2 connection to a JDBC Type 4 connection, remove the database alias names and refer to the databases directly. This is required because of a limitation in the DB2 Universal JDBC driver.

**Prerequisites**

- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties
- Configure WebSphere Portal to use DB2
- Configuring DB2 for large file handling in Web Content Management

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2.

   ```
   /home/db2inst1/sqllib/db2profile
   ```

   where `db2inst1` represents your database instance.

   **Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.
3. Enter the following commands to validate configuration properties.

   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```
4. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td><code>/stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td><code>/stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

6. Change to the directory `wp_profile_root/ConfigEngine`.

7. To change from one supported driver to the other, run the following task to connect the database, including only the domains that require the switch:

```
```

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

1. Installing DB2 for z/OS
   View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

2. Creating users
   Complete this procedure to set up users for IBM DB2 Universal Database™ for z/OS® to work with IBM WebSphere Portal.

3. Creating remote databases
   A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

4. Optional: Creating the Java Content Repository database
   View information on setting up your Java Content Repository database to work with WebSphere Portal.

5. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

6. Configuring WebSphere Portal to use DB2 for z/OS
   View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2 for z/OS

View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

The following prerequisites must exist separately from the WebSphere Portal installation:

- If you are using the DB2 Legacy Type 2 JDBC driver, configure your DB2 Connect client with the following commands:
  
  - `db2 update dbm cfg using tp_mon_name WAS`
  - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name for the machine where the DB2 Connect client is installed (same as portal machine).

- If you are using the DB2 Legacy Type 2 JDBC driver, enable extended shared memory usage with the following commands:
  
  - `export EXTSHM=ON`
  - `db2set DB2ENVLIST=EXTSHM`
  - `db2start`

  To make the change permanent, you must add the environment variable by adding the following to the `profile.env` file:

  ```
  DB2ENVLIST='EXTSHM'
  ```

  in `/home/db2inst/sqllib/userprofile`

  add: `export EXTSHM=ON`

  **Note:** The shell must be reopened before restarting DB2 for z/OS.

- Both type 2 and type 4 drivers are supported. If you are using the DB2 Legacy Type 2 JDBC driver, the DB2 Connect client must be installed on the same machine as WebSphere Portal to connect to the remote database.

- The DB2 subsystem must be on a supported z/OS platform.

- Update the BP8K0 catalog bufferpool to 35,000 buffers before performing database transfer. You should change this value based on your environment. The SYSIBM.SYSDATABASE table resides in this bufferpool and is used extensively by DB2 for z/OS during database transfer.

To use DB2 for z/OS as the database software for WebSphere Portal, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions. Refer to the Planning for DB2 for z/OS topic for additional considerations for configuring DB2 for z/OS as the WebSphere Portal database.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS  
**Next topic:** Creating users
Creating users

Complete this procedure to set up users for IBM® DB2 Universal Database™ for z/OS® to work with IBM WebSphere® Portal.

Before you begin: You should have completed Installing DB2 for z/OS.

- Prerequisites

- Installing DB2 for z/OS

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

- If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, you must create a unique database user for each WebSphere Portal instance. By default all database table names include the name of the database user used to access the data. Therefore, to prevent table name conflicts, you must create a unique database user for each WebSphere Portal instance on the shared DB2 for z/OS subsystem.

- Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Use the following steps to grant access permissions to the database users. Repeat these steps for each WebSphere Portal instance you are setting up.

1. Create all database user IDs in the security product you are using on z/OS. For jcrschema, the database schema name for IBM Java Content Repository data, create a group and connect it to the database user ID for Java Content Repository data, jcr. The following sample shows the RACF definition of such a user ID and group, where jcr is the database user ID for Java Content Repository data, yourDefaultUserGroup is your default RACF group for database user IDs, jcrschema is the database schema name for Java Content Repository data, and yourDefaultGroup is your default RACF group for groups. If you have some other security product such as Top Secret or ACF2 instead of RACF, translate the sample RACF definition into the appropriate syntax before running the job.

   ```
   ADDUSER jcr DFLTGRP(yourDefaultUserGroup) NAME('WAS DB2 ACCESS USER')
   PW USER(jcr) NOINTERVAL
   ALU jcr PASSWORD(********) NOEXPIRED
   ADDGROUP jcrschema SUPGROUP(yourDefaultGroup)
   CONNECT jcr GROUP(jcrschema)
   ```

2. Run the following SQL statements using a tool like SPUFI while logged on to the DB2 subsystem to grant appropriate rights on the newly created databases. If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, be sure to use the database user associated with the WebSphere Portal instance you are setting up. Where:
* releasenameonzos, communitynameonzos, customizationnameonzos, and releaseusr, communityusr, customizationusr represent the databases and database users, respectively, of the WebSphere Portal instance you are setting up. (These users must be created on the host system.)

* jcrdbnameonzos and jcr are the database and database user, respectively, for Content Repository data.

* fdbkdbnameonzos and feedback are the database and database user, respectively, for Feedback data.

* lmdbnameonzos and lmdbusr are the database and database user, respectively, for Likeminds data.

* jcrschema is the database schema name for Content Repository data.

3. Grant the necessary access rights to all users who might require them. Depending on the architecture that you choose, these users might include Java Content Repository and Feedback users.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Previous topic:** Installing DB2 for z/OS

**Next topic:** Creating remote databases
Creating remote databases

A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

Before you begin, complete the following prerequisites:

- These instructions assume that you will use a local IBM® DB2 Universal Database™ Enterprise Server Edition Connect to connect to a remote IBM DB2 Universal Database for z/OS® server, and that IBM WebSphere® Application Server, WebSphere Portal, and DB2 Connect will be installed on the same machine.
- To run SQL statements, you can use a tool like SPUFI. The specified statements include CREATE STOGROUP, CREATE DATABASE and CREATE TABLESPACE. For CREATE STOGROUP you have to replace the icmvolumes and icmvcat variables with volume serial numbers and a catalog name for your environment. For CREATE TABLESPACE you can specify a specific BUFFERPOOL. Refer to the DB2 for z/OS SQL Reference for a description of these options.
- Ensure that a TEMP database is created for your subsystem. You can use the following statements to create a TEMP database:

```
CREATE DATABASE db_name AS TEMP;
CREATE TABLESPACE ts_name IN db_name;
```

- Log on to the DB2 subsystem on the host server. DB2 system administrator rights are needed to create the databases.
- Replace variables as follows:
  - releasenameonzos, communitynameonzos, and customizationnameonzos are the WebSphere Portal databases for WebSphere Portal and Member Manager data.
  - fdbkdbnameonzos and fdbkdtbs are the database and table space, respectively, for Feedback data.
  - lmdbnameonzos and lmdtbs are the database and table space, respectively, for LikeMinds data.
- Because large objects are stored in columns that can become very large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for tablespaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see Technote 1306637, Managing LOB logging in DB2 for z/OS.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users

Use the following steps to set up WebSphere Portal with a remote instance of DB2 for z/OS. Refer to Planning for DB2 for z/OS for a list of databases and table space names. If you are configuring multiple WebSphere Portal instances to use a single DB2 subsystem, be sure to use the database and table space names associated with the WebSphere Portal instance you are setting up.

1. CREATE DATABASE releasenameonzos CCSID UNICODE;
2. CREATE DATABASE communitynameonzos CCSID UNICODE;
3. CREATE DATABASE customizationnameonzos CCSID UNICODE;
4. Execute the steps in the topic Creating the Java Content Repository database.
5. CREATE DATABASE fdbkdbnameonzos CCSID UNICODE;
6. CREATE TABLESPACE fdbkdtbs IN fdbkdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500 LOCKSIZE ROW;
7. CREATE DATABASE lmdbnameonzos CCSID UNICODE;
8. CREATE TABLESPACE lmdbts IN lmdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500;

**Related Information**

- Managing LOB logging in DB2 for z/OS
Creating the Java Content Repository database

View information on setting up your Java Content Repository database to work with WebSphere Portal. First, you need to create multiple databases for scalability.

The IBM Java Content Repository database grows in size as the IBM® WebSphere® Portal server is used. To support this growth, which includes the dynamic creation of many new tables within the database, the WebSphere Portal server allows you to create multiple databases within a single IBM DB2 Universal Database™ for z/OS® subsystem. A minimum of two databases is recommended, but more can be created if necessary. A single database setup is not recommended; it will quickly become constrained. See the Performance guides on the product documentation Web site for more information.

Each database that is created must begin with a common prefix; there is no convention required for the remainder of the name. For example, to create xx number of databases, you may choose to use the following commands:

```
CREATE DATABASE JCRDB01
CREATE DATABASE JCRDB02
...
CREATE DATABASE JCRDBxx
```

In this case, JCR is the common prefix. You also have to select a maximum number of user-defined tables (UDT) that each database will be allowed to hold; the recommended value is 400.

- **Prerequisites**
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

A sample script of the commands that you can use to create the Java Content Repository database in your DB2 for z/OS installation is shown below. The sample demonstrates the creation of a single database. To follow the recommendation of creating at least two databases, duplicate the commands for each additional database as indicated below. Find a template of these commands in the file `PortalServer_root` installer/wp.config/config/templates/db/db2_zos/jcr_sample.sql.

**Notes:**
- It is not necessary to duplicate every tablespace definition in every database.
- In order to run the commands shown in the sample, you must know the database name and the IDs of the MVS volumes where the Java Content Repository database tables will be stored.
- Edit the template file for your installation environment before running the commands shown in the sample:
  - Replace `jcrdbnameX` with the name of the database. Remember that each database name must begin with a common prefix.
  - Replace `stogroup` with the name of your storage group.
  - Replace `icmvolumes` with the IDs of the MVS volumes where the Java Content Repository database tables will be stored. These values are assigned by the database administrator.
  - Replace `icmvcat` with the name of the virtual catalog.
  - Replace `jcr` with the name of database user ID.
  - Replace `4kbp` with the name of your 4K bufferpool.
  - Replace `32kbp` with the name of your 32K bufferpool.
  - Replace `jcrschema` with the schema name of your Java Content Repository domain.
--DROP DATABASE jcrdbnameX
--DROP STOGROUP stogroup
--DROP ALIAS jcrschema.ICMFICTITIOUS

CREATE STOGROUP stogroup VOLUMES (icmvolumes) VCAT icmvcat

GRANT USE OF STOGROUP stogroup to jcr

CREATE DATABASE jcrdbnameX STOGROUP stogroup BUFFERPOOL 4kbp INDEXBP 4kbp CCSID UNICODE

Note: The following two tablespace commands must be created in every database:

CREATE TABLESPACE ICMLFQ32 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 32kbp CCSID UNICODE

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Creating remote databases
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.
- When using IBM® DB2 Universal Database™ for z/OS® as a data store, WebSphere Portal requires that its indexes are not padded. Therefore, you must set the DSNZPARM parameters to RETVLCFK=NO or PADIX=NO, or both.

**Prerequisites**
- Installing DB2 for z/OS
- Creating users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each .tablespace entry in the mapping file. Assignments to .indexspace entries are ignored. The table space name must be qualified by the database name and prepended by the keyword IN and a space. For example: community.COMP_INST.tablespace=IN COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Previous topic:** Creating the Java Content Repository database

**Next topic:** Configuring WebSphere Portal to use DB2 for z/OS
Configuring WebSphere Portal to use DB2 for z/OS

View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.

   A. Locate the file /home/db2inst1/sqllib/cfg/db2cli.ini.
   B. Add the following to the end of the file. Leave an empty line after returnAliases=0.

```
[COMMON]
DYNAMIC=1
ReturnAliases=0
```

2. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.

3. Enter the following commands to validate configuration properties...

```
./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
```

4. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

6. Transfer the database:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory wp_profile_root/ConfigEngine.

   B. Enter the following command:

```
./ConfigEngine.sh database-transfer -DWasPassword=password
```

**Note:** To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter...
the following command: 

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files and then repeat this step.

7. From the command line processor, reset the check pending status on the WebSphere Portal table spaces listed here.

CHECK DATA is a DB2 batch utility that is invoked through JCL or through the DB2 utility panels. Type the following utility commands to check pending status:

- `check data tablespace releasenameonzos.TS320A`
- `check data tablespace releasenameonzos.TS280A`
- `check data tablespace releasenameonzos.TS300A`
- `check data tablespace releasenameonzos.TS2110A`
- `check data tablespace releasenameonzos.TS830A`
- `check data tablespace communitynameonzos.TS8000B`
- `check data tablespace communitynameonzos.TS8011B`
- `check data tablespace communitynameonzos.TS280B`
- `check data tablespace customizationnameonzos.TS2110C`
- `check data tablespace jcrdbnameonzos.ICMSPQ04`
- `check data tablespace jcrdbnameonzos.TS2110D`

where releasenameonzos, communitynameonzos, and customizationnameonzos are the names of your WebSphere Portal databases, and jcrdbnameonzos is the name of your JCR database. Refer to the Utility Guide and Reference for DB2 for z/OS for additional details.

8. Run the RUNSTATS utility as shown in the following example:

```
LISTDEF JCRDBZOS INCLUDE TABLESPACE JCRDBZOS.* BASE
RUNSTATS TABLESPACE LIST JCRDBZOS INDEX(ALL) KEYCARD TABLE(ALL)
LISTDEF JCRDB01 INCLUDE TABLESPACE JCRDB01.* BASE
RUNSTATS TABLESPACE LIST JCRDB01 INDEX(ALL) KEYCARD TABLE(ALL)
...
```

9. Start the WebSphere Application Server.

10. Verify that the WebSphere Portal application server is running by opening the following URL in a browser:

```
http://hostname.companyname.com:port_number/wps/portal
```

where hostname.companyname.com is the fully qualified host name of the machine where WebSphere Portal is running and port_number is the transport port that is created by WebSphere Application Server.

If you have performed database transfer in a clustered environment, you must explicitly copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node on which the database-transfer task was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values specified in the icm.properties file.

1. Stop the portal server on the secondary node.
2. Copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node and replace the icm.properties file on the secondary node with the new file from the primary node.
3. Start the portal server on the secondary node.
Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

1. Installing Oracle
   View information on how to install Oracle for use with WebSphere Portal.

2. Creating users
   View the steps to set up users for Oracle to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle databases to work with WebSphere Portal.

4. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configure WebSphere Portal to use Oracle
   This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle

View information on how to install Oracle for use with WebSphere Portal.
You can use Oracle as the database software. You must install Oracle separately and before performing a database transfer.
Refer to Oracle product documentation for installation instructions.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Next topic:** Creating users
Creating users

View the steps to set up users for Oracle to work with WebSphere Portal.

Before you begin:
- You should have installed Oracle.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**
- Installing Oracle

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Start the Oracle SQL command line processor 'SQL*Plus' by entering `sqlplus /nolog` on the operating system command prompt
2. Log in to the Oracle database by executing command `connect user/password@database name`. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.
3. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, or customization.
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following commands in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects. All names must be in lower case.

   ```sql
   SQL> create user releaseusr identified by password
       default tablespace user_tablespace
       temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO releaseusr;
   SQL> create user communityusr identified by password
       default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO communityusr;
   SQL> create user customizationusr identified by password
       default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO customizationusr;
   SQL> create user jcr identified by password
       default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO jcr;
   ```
4. Connect to the Feedback database:
   A. Enter the following command: `SQL> connect`
B. Enter user-name: username/password@dbname where 'username' is an existing administrative user in the database. For example, system/manager@fdbkdb will log the administrative user system with a password of manager into the fdbkdb database.

C. Create the Feedback user:

```
SQL> create user feedback identified by password
    
default tablespace user_tablespace
    
temporary tablespace temp_tablespace;
    
GRANT UNLIMITED TABLESPACE TO feedback
```

D. Log out of the command line tool using the command SQL> exit.

5. Connect to the LikeMinds database:

A. Enter the following command:
```
SQL> connect
```

B. Enter user-name: username/password@dbname, where 'username' is an existing administrative user in the database. For example, system/manager@lmdb will log the administrative user system with a password of manager into the lmdb database.

C. Create the LikeMinds user:

```
SQL> create user lmdbusr identified by password
    
default tablespace user_tablespace
    
temporary tablespace temp_tablespace;
    
GRANT UNLIMITED TABLESPACE TO lmdbusr
```

D. Log out of the command line tool using the command SQL> exit.

6. Perform the following steps to verify that you can connect to the database with the user ID and password that you just created:

A. Enter the SQL> connect command to connect to the content database.

B. Enter user-name: username/password@dbname, where 'username' is an existing administrative user in the database. For example, system/manager@jcrdb will log the administrative user system with a password of manager into the Oracle database.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Installing Oracle

**Next topic:** Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal.

For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- All databases must be created manually before configuring WebSphere Portal.
- The Oracle databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:
  
  
  - `db_block_size = 8192` bytes
  - `db_cache_size = 307,200` bytes
  - `db_files = 1024` files
  - `log_buffer = 65536` bytes
  - `open_keywords = 1500` keywords
  - `pga_aggregate_target = 204,800` bytes
  - `pre_page_sga = true`
  - `processes = 300` processes
  - `shared_pool_size = 204,800` bytes

  **Note:** If you are using IBM Java Content Repository, the `open_keywords` value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the `parallel_max_servers` to 1200.
- The Oracle parameter `CURSOR_SHARING` allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for `CURSOR_SHARING`, which are as follows:
  
  **FORCE**
  
  When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.

  **EXACT**
- When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

**Prerequisites**

- Installing Oracle
- Creating users

Parent topic: Configuring WebSphere Portal to use Oracle

Previous topic: Creating users

Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and Like Minds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=customdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
- `dbdomain DbType`
- `dbdomain DbName`
- `dbdomain DbUrl`
- `dbdomain DbSchema`

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.

   A. For `dbdomain DbType`, type `oracle`.
   B. For `dbdomain DbName`, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the `dbdomain DbName` property.
   C. For `dbdomain DbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The `dbdomain DbName` should be the same value used for the `dbdomain DbSchema` restricted.

   **Restriction:** The value for `dbdomain DbSchema` must equal the value for `dbdomain DbUser`.
   D. For `dbdomain DataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For `dbdomain DbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:**
      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
F. For `dbdomain.DbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomain.DbUser` must equal the value for `dbdomain.DbSchema`.

G. For `dbdomain.DbPassword`, type the password for the database administrator.

H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.

I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

B. For `source.domainDbName`, type the name of the database domain you are currently using.

C. For `source.domainDbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domainDbUrl`, type the url currently used to access your database.

F. For `source.domainDbUser`, type the name of the user accessing this database.

G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `oracle.dbDriver`, type the name of the class that SqlProcessor uses to import SQL files.

   B. For `oracle.dbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `oracle.jdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`.

3. To create the database users, type the following command:

   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `<WP_root>/base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Related tasks**  
Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '/&dbpath./&jcrdb./data/icmlfq32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '/&dbpath./&jcrdb./data/icmlnf32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLVFQ04 datafile '/&dbpath./&jcrdb./data/icmlvfq04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '/&dbpath./&jcrdb./data/icmsfq04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '/&dbpath./&jcrdb./index/icmlsndx_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   ```

   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.

   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.

   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Setting up databases

**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tables spaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tables spaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
     - `release`
     - `community`
     - `customization`
     - `jcr`
     - `feedback`
     - `likeminds`
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `TABLESPACE` and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - `Windows`: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

Parent topic: Configuring WebSphere Portal to use Oracle
Previous topic: Creating JCR table spaces
Next topic: Configure WebSphere Portal to use Oracle
Configure WebSphere Portal to use Oracle

This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

Tips:
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory \wp_profile_root\ConfigEngine.
2. Enter the following commands to validate configuration properties: 
   .\ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   .\ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
3. From the same command prompt as the previous steps, change to the directory \wp_profile_root\bin.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>
5. **Transfer the database**:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   **A.** Change to the directory `wp_profile_root/ConfigEngine`.
   
   **B.** Enter the following command:
   
   ```
   ./ConfigEngine.sh database-transfer -DWasPassword=password
   ```
   
   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   
   ```
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```
   
   **C.** After running this task, a message is added to the log files to verify that this task was successful. Check the log files.
   
   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

   ```
   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
   ```

7. Change to the directory `wp_profile_root/bin`.

8. Enter the following command to start the WebSphere Portal server:

   ```
   ./startServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```

---

   View information on how to install Oracle RAC for use with WebSphere Portal.

2. Create users
   View the steps to set up users for Oracle RAC to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal.

4. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configuring WebSphere Portal to use Oracle RAC
   This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:
- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon_(GSD), oracle listeners, and agents.
  - `$ gsdctl start`
  - `$ lsnrctl start`
  - `$ agentctl start`

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle RAC

Next topic: Create users
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:

- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**

- Installing Oracle RAC

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects:

   ```sql
   SQL> create user username identified by password
       default tablespace user_tablespace
       temporary tablespace temp_tablespace;
   ```

   **Tip:** Balance the storage of user objects among tablespaces to prevent running out of space with overuse of `user_tablespace`. Also consider increasing the size of `user_tablespace` when handling a high volume of users.

2. Log in by entering the command `sqlplus` in SQL*Plus:

3. Enter the command `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example: system/manager@wpsdb will log the administrative user system with a password of manager into the wpsdb database.

4. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults.

   ```sql
   SQL> create user releaseusr identified by password;
   SQL> create user communityusr identified by password;
   SQL> create user customizationusr identified by password;
   SQL> create user jcr identified by password;
   ```

5. Connect to the content database by entering the command `SQL> connect`.

6. Enter the following, where `username` is an existing administrative user in the database: `user-name: username/password@dbname`. For example, `system/manager@jcrdb` will log the administrative user system with a password of manager into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the `jcr` user, grant all necessary privileges. If you do not grant privileges, you will receive the error `ICMADMIN lacks CREATE SESSION Privilege logon denied`. 

---

**WebSphere Portal, Version 6.1.5**

**Operating systems:** AIX, HP-UX, i5/OS, Linux, Solaris, Windows
when you try to connect with the \texttt{jcruser}:

```
SQL> create user jcr identified by password default tablespace users temporary tablespace temp;
```

8. Connect to the Feedback database:
   A. Enter the following command:

   ```
   SQL> connect
   ```

   B. Enter \texttt{user-name: username/password@dbname} where \texttt{username} is an existing administrative user in the database.

   For example, system/manager@fdbkdb will log the administrative user system with a password of manager into the fdbkdb database.

9. Create the Feedback user:

   ```
   SQL> create user feedback identified by password default tablespace users temporary tablespace temp;
   ```

10. Connect to the LikeMinds database:

    ```
    SQL> connect
    ```

11. Enter \texttt{user-name: username/password@dbname}, where \texttt{username} is an existing administrative user in the database. For example, system/manager@lmdb will log the administrative user system with a password of manager into the lmdb database.

12. Create the LikeMinds user:

    ```
    SQL> create user lmdbusr identified by password default tablespace users temporary tablespace temp;
    ```

13. Log out of the command line tool using the command \texttt{SQL> exit}.

\textbf{Parent topic:} Configuring WebSphere Portal to use Oracle RAC  
\textbf{Previous topic:} Installing Oracle RAC  
\textbf{Next topic:} Creating databases
Creating databases

View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal. When creating Oracle RAC databases for use with WebSphere Portal, you should consider the following information:

- The Oracle RAC databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle RAC server will be remote or local to the WebSphere Portal installation.
- If using an earlier version of Oracle RAC (9i or earlier), ensure that Oracle RAC JVM is also installed.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle RAC database in order for WebSphere Portal to communicate with the IBM Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes are:

  - `db_block_size` = 8192 bytes
  - `db_cache_size` = 314,572,800 bytes
  - `db_files` = 1024 files
  - `log_buffer` = 65536 bytes
  - `open_cursors` = 1500 cursors
  - `pga_aggregate_target` = 209,715,200 bytes
  - `pre_page_sga` = true
  - `processes` = 300 processes
  - `shared_pool_size` = 209,715,200 bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the IBM Java Content Repository schema.

**Prerequisites**

- Installing Oracle RAC
- Create users

Refer to the following instructions to create tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create the tablespaces. **Important:** You must use the same tablespace names listed in the commands. The tablespace names cannot be customized or modified.

   A. Find and edit the SQL script `jcr_ora_tablespaces.sql` in the directory `/ConfigEngine/work/db/oracle`.
   
   B. In the `define` section, replace the following variables with the values from your environment:
      - `jcrdb`
        - Name of the database you created to store user data.
      - `logfile`
        - Location to store the log file.
      - `dbpath`
        - Directory where you created the database.
   
   C. Set the size, autoextend, and maxsize values according to your environment. For example, you may want to change the maxsize to a set value rather than UNLIMITED. Consult your Database Administrator for more info.
D. Execute the following SQL script:

- The DBA or a user with sufficient credentials (CREATE tablespace) must execute the script.
- The script will prompt for the database username and password.

```
# sqlplus
SQL > @jcr_ora_tablespaces.sql
```

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Create users  
**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

TIP: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
1. If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.

   A. For dbdomainDbType, type oracle.
   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomainDbUrl property.
   C. For dbdomainDbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomainDbName should be the same value used for the dbdomainDbSchema
      Restriction: The value for dbdomainDbSchema must equal the value for dbdomainDbUser.
   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
F. For `dbdomain.DbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomain.DbUser` must equal the value for `dbdomain.DbSchema`.

G. For `dbdomain.DbPassword`, type the password for the database administrator.

H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.

I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

B. For `source.domainDbName`, type the name of the database domain you are currently using.

C. For `source.domainDbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domainDbUrl`, type the url currently used to access your database.

F. For `source.domainDbUser`, type the name of the user accessing this database.

G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

A. For `oracle.DbDriver`, type the name of the class that `SqlProcessor` uses to import SQL files.

B. For `oracle.DbLibrary`, type the directory and name of the `.zip` or `.jar` file that contains the JDBC driver class.

C. For `oracle.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

**Prerequisites**
- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties

1. On the database server, make sure that the folder db_1 contains the subfolders your_oracle_instance/data and your_oracle_instance/index. If this folder hierarchy does not exist, create it manually before you run the setup-database task. The setup-database task requires these folders to create database users. If these folders do not exist, the setup-database task will fail.

2. Change to the directory wp_profile_root/ConfigEngine

3. To create the database users, type the following command:

   ```
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires db_owner permission for the database user. The script that creates users is invoked by the configuration task setup-database and is located in the installation directory of WebSphere Portal:

   `<WP_root>/base/wp.db.impl/config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**
Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `'.'` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb./data/ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '&dbpath./&jcrdb./data/ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb./data/ICMVFPQ04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb./data/ICMSFPQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '&dbpath./&jcrdb./index/ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   
   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Setting up databases  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `TABLESPACE` and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`

   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
UNIX: /ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Creating JCR table spaces
Next topic: Configuring WebSphere Portal to use Oracle RAC
Configuring WebSphere Portal to use Oracle RAC

This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**Prerequisites**
- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

**Tips:**
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:
  
  `jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=PRIMARY_NODE_HOSTNAME) (PORT=1521)) (ADDRESS=(PROTOCOL=TCP) (HOST=SECONDARY_NODE_HOSTNAME) (PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICE))`.  

- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**
1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties:
   ```bash
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:
   ```bash
   ./stopServer.sh server1 -username admin_userid -password admin_password
   ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```
5. Transfer the database:**Note**: Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory `wp_profile_root/ConfigEngine`.
   B. Enter the following command:
      ```bash
      ./ConfigEngine.sh database-transfer -DWasPassword=password
      ```
      **Note**: To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
      ```bash
      ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
      ```
   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.
6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:
   ```sql
   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
   ```
7. Specify the JDBC URL to connect to the cluster:
   A. Login to the WebSphere Application Server Administrator Console
   B. Navigate to **Resources > JDBC Providers**
   C. If there is a value in the Node field, remove it and click **Apply**.
   D. For each Oracle JDBC provider, repeat the following steps:
      1. Click the provider name.
      2. Select **Data Sources**.
      3. Click the name of the data source.
      4. Under the Oracle data source properties, modify the URL attribute according to Oracle RAC configuration:
         ```sql
         jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))(ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME)))
         ```
      5. Save your changes
8. Change to the directory `wp_profile_root/bin`.
9. Enter the following command to start the WebSphere Portal server:
   ```bash
   ./startServer.sh WebSphere_Portal
   ```

Configuring WebSphere Portal to use SQL Server

View information on installing and setting up SQL Server to work with WebSphere Portal.

1. Installing SQL Server
   View the steps to install SQL Server for use with WebSphere Portal.

2. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc DbType.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

3. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

4. Optional: Assigning custom filegroups
   The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

5. Configuring WebSphere Portal to use SQL Server 2005
   This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing SQL Server

View the steps to install SQL Server for use with WebSphere Portal. Before you begin this task, complete the following prerequisites:

- You should have completed reviewing the Planning for SQL Server topic.
- You must install SQL Server separately from WebSphere Portal.
- WebSphere Portal requires either the DataDirect Connect for JDBC 3.7 JDBC driver or the Microsoft SQL Server JDBC Driver.
- You can obtain the DataDirect Driver from DataDirect Technologies. The JDBC driver consists of two parts: the JDBC driver libraries and JTA libraries. The JDBC driver libraries must be put on the WebSphere Portal system, while the JTA libraries are intended for SQL Server.
- You can obtain the Microsoft SQL Server JDBC Driver from Microsoft. See the Microsoft SQL Server product documentation for installation details.

The following section provides instructions for installing SQL Server for use with IBM® WebSphere® Application Server and WebSphere Portal. These steps are the same for both the DataDirect and Microsoft drivers unless noted.

1. Install SQL Server and all required patches.
2. Select the authentication mode for this installation:
   - Windows Authentication Mode
   - Mixed Mode (Windows Authentication and SQL Server Authentication)
     Either authentication mode allows the user who is specified as the database administrator in the wkplc_comp.properties file to log in to the SQL server. Mixed Mode authentication allows either a Windows user or a SQL server user, or both, to log in to the SQL Server.
3. In the SQL Server Setup panel, Components to Install, select the following components, which are required services for WebSphere Portal:
   - SQL Server Database Services
     - Integration Services The option Integration Services creates the directory DTS/Binn, where you will need to copy files when you install Microsoft SQL Server JDBC drivers and enable XA connections.
4. Complete the installation using SQL Server documentation as a guide.
5. Enable TCP/IP connectivity in the SQL Server Configuration Manager.
6. Install the JDBC driver using one of these methods:
   - Installing DataDirect Connect for JDBC drivers on UNIX
   - Installing DataDirect Connect for JDBC drivers on Windows
   - Installing Microsoft SQL Server JDBC drivers and enabling XA connections
7. Network the connections for MSDTC in the Windows Component Services as described in Microsoft Help and Support.
8. Start SQL Server.

Installing DataDirect Connect for JDBC drivers on UNIX

1. Purchase and download DataDirect Connect for JDBC and save file 360connectjdbc.jar in a temporary work directory.
To create the required files, run the following command from the directory that contains 360connectjdbc.jar:

```
jar -xvf 360connectjdbc.jar
```

Run `./installer.sh` in the same directory.

When installation is complete, change directory to `/installation/lib`, where `installation` is the directory in which you installed the DataDirect Connect for JDBC drivers.

Run the following command to change the permissions on the JAR files in the `installation/lib` directory:

```
chmod 777 *.jar
```

Change the ownership and group of these files by running the following commands in the `installation/lib` directory:

```
chgrp system_grp *.jar
chown root *.jar
```

Where `system_grp` is the system group as labeled by your operating system.

Installing Microsoft SQL Server JDBC drivers and enabling XA connections

1. Download and install the Microsoft SQL Server JDBC driver.

2. Copy file `sqljdbc_xa.dll` from the `xa` subdirectory to the `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll` directory of the SQL Server installation.

3. Start the database server.

4. Ensure that the Distributed Transaction Coordinator has been started. The status can be verified in the list of services in the Computer Management console.

5. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.

6. Select File > Open > File and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.

7. Execute the script by selecting Query > Execute. Note: Any warnings that appear in the messages section of the application window that say that stored procedures cannot be found can be safely ignored.

8. For Microsoft SQL Server JDBC drivers: If you are running Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003, refer to the Registry Entries Are Required for XA Transaction Support document for information on a new security constraint and how to set SQL Server on Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003. Create an additional value in the Windows registry for WebSphere Portal by following these steps:

   A. Open the Windows Registry Editor (regedit) and navigate to the element `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XA\DLL`

   B. From the menu bar, select Edit > New > String Value to create a new parameter named `sqljdbc_xa.dll` in that element.

   C. Change the value of the new parameter to the location of the `sqljdbc_xa.dll` file copied in Step 2 above, for example: `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll`

Parent topic: Configuring WebSphere Portal to use SQL Server

Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

**Prerequisites**

- Installing SQL Server

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:

- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:

  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkidb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:

  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:

  - `dbdomain.DbType`
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If \texttt{DbUser}, \texttt{DbUrl}, and \texttt{DbPassword} are not the same across domains, the value for \texttt{DataSourceName} must differ from the \texttt{DataSourceName} of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
\begin{itemize}
  \item \texttt{wp_profile_root}/ConfigEngine/properties/wkplc.properties
  \item \texttt{wp_profile_root}/ConfigEngine/properties/wkplc_comp.properties
  \item \texttt{wp_profile_root}/ConfigEngine/properties/wkplc_dbtype.properties
\end{itemize}
Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In \texttt{wkplc_comp.properties}, most properties are repeated for each domain.

2. Use a text editor to open the properties file \texttt{wkplc_comp.properties} and modify the values to correspond to your environment.
\begin{itemize}
  \item A. For \texttt{dbdomainDbType}, type \texttt{sqlserver2005}.
  \item B. For \texttt{dbdomainDbName}, type the name of the WebSphere Portal domain database. \textbf{Note:} This value is also the database element in the \texttt{dbdomainDbUrl} property.
  \item C. For \texttt{dbdomainDbSchema}, type the schema name of the database domain. \textbf{Note:} Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
  \item D. For \texttt{dbdomainDataSourceName}, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
    \begin{itemize}
      \item releaseDS
      \item communityDS
      \item customizationDS
      \item jcrDS
      \item lmdbDS
      \item feedback
    \end{itemize}
  \item E. For \texttt{dbdomainDbUrl}, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. \textbf{Note:} The database element of this value should match the value of \texttt{DbName}.
  \item F. For \texttt{dbdomainDbUser}, type the user ID for the database administrator.
  \item G. For \texttt{dbdomainDbPassword}, type the password for the database administrator.
  \item H. For \texttt{dbdomainDBA_DbUser}, type the database administrator user ID for privileged access operations during creation of the database.
  \item I. For \texttt{dbdomainDBA_DbPassword}, type the database administrator password for privileged access operations during creation of the database.
  \item J. For \texttt{dbdomainDbHome}, type the root location for the database. \textbf{Note:} This value is the location to store the database files locally.
  \item K. For \texttt{dbdomainAdminUrl}, type the sqlserver URL without a database attached. This value is used to connect to the server for database administration operations.
  \item L. For \texttt{dbdomainDbHostName}, type the hostname of the database.
\end{itemize}

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in \texttt{wkplc_comp.properties}. \textbf{Important:} The default values for the following parameters are
set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

B. For `source.domainDbName`, type the name of the database domain you are currently using.

C. For `source.domainDbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domainDbUrl`, type the url currently used to access your database.

F. For `source.domainDbUser`, type the name of the user accessing this database.

G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `sqlserver2005.DbDriver`, type the name of the class that `SqlProcessor` uses to import SQL files.

   B. For `sqlserver2005.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `sqlserver2005.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

   D. For `sqlserver2005.DbConnectionPoolDataSource`, type the name of the implementation class of the connection pool data source.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use SQL Server  
**Previous topic:** Installing SQL Server  
**Next topic:** Setting up databases
Setting up databases
This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

- Prerequisites
  - Installing SQL Server
  - Modifying database properties

1. Change to the directory `wp_profile_root/ConfigEngine`
2. To create the databases, type the following command:
   ```bash
   ./ConfigEngine.sh create-database -DWasPassword=password
   ```
3. To create the database users, type the following command:
   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:
   `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`

Parent topic: Configuring WebSphere Portal to use SQL Server
Previous topic: Modifying database properties
Next topic: Assigning custom filegroups

Related tasks
Create users and databases for SQL Server 2005 on AIX and UNIX
Assigning custom filegroups

The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin:

- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating filegroups refer to the documentation for the database.

**Prerequisites**

- Installing SQL Server
- Modifying database properties
- Setting up databases

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

1. Determine the names of your custom filegroups.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces that specifies the table space and index space for each property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.indexspace.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword ON and a space. For example: community.COMP_INST.tablespace=ON COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
   - UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
   - i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
Configuring WebSphere Portal to use SQL Server 2005

This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005.

As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing SQL Server
  - Modifying database properties
  - Setting up databases

Tips:
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.
2. Enter the following commands to validate configuration properties.
   ```
   ../ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ../ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
4. Stop both WebSphere Application Server and the WebSphere Portal server:
   ```
   Option                      Description
   WebSphere Application Server ./stopServer.sh server1 -username admin_userid -password admin_password
   WebSphere Portal            ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```
5. Transfer the database: Note: Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory wp_profile_root/ConfigEngine.
B. Enter the following commands:
```
./ConfigEngine.sh database-transfer -DWasPassword=password
```

**Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. Change to the directory `wp_profile_root/bin`.

7. Enter the following command to start the WebSphere Portal server:
```
./startServer.sh WebSphere_Portal
```

8. Update the SQL Server 2005 statistics for Portal, and JCR databases by opening SQL Server Management Studio, selecting **New Query**, and running the following query:
```
use db_name
exec sp_updatestats @resample='resample';
```

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Assigning custom filegroups
Verifying databases
After you configure IBM® WebSphere® Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

- **Prerequisites**
  - [+] Technotes for database connectivity issues

You can verify the database connection using IBM WebSphere Application Server or by opening WebSphere Portal in a browser.

- To verify that the WebSphere Portal application server is running by using WebSphere Application Server, complete these steps:
  1. Open the WebSphere Application Server administrative console by entering the following address in a browser:
     ```
     http://hostname.example.com:10027/ibm/console
     ```
     where `hostname.example.com` is the fully qualified host name of the machine where WebSphere Portal is running and `10027` is the default transport port that is created by WebSphere Application Server.
  2. Log into the administrative console.
  3. Depending on your version of WebSphere Application Server, click the appropriate option:
     - For **WebSphere Application Server Version 6.1**: Click Resources & JDBC Providers.
     - For **WebSphere Application Server Version 7.0**: Click Resources > JDBC > JDBC Providers
  4. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
  5. Select the name of the data source that is defined in `wkplc_comp.properties`. The default data source is `wpdbDS`.
  6. Select the name of the JDBC provider that is specified in `wkplc_dbtype.properties`. The default JDBC provider is `wpdbJDBC_dbtype`, where `dbtype` is replaced by the value that matches your environment.
  7. Click **Test Connection** to verify the database connection. If configuration parameters have been changed, you might need to restart WebSphere Application Server for the test to complete.

- To verify that the WebSphere Portal application server is running by opening WebSphere Portal in a browser, enter the following URL in a supported browser:
  ```
  http://hostname.example.com:10040/wps/portal
  ```
  where `hostname.example.com` is the fully qualified host name of the machine where WebSphere Portal is running and `10040` is the default transport port that is created by WebSphere Application Server.

**Parent topic:** Configure WebSphere Portal to use a remote database
Configuring the primary node to communicate with the deployment manager on HP-UX

After installing IBM® WebSphere® Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

- Prerequisites
  - Installing WebSphere Portal on HP-UX on the primary node
  - Configure WebSphere Portal to use a remote database

Perform the following steps to configure WebSphere Portal to communicate with the deployment manager:

1. Run the `./ConfigEngine.sh collect-files-for-dmgr -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory of the primary node, to create an archive or compressed file containing all the files which need to be copied to the Deployment Manager. **Note:** The archive or compressed file will be placed in the `wp_profile_root/filesForDmgr` directory and the file will be called `filesForDmgr.zip`.

2. Stop the deployment manager.

3. Expand the `filesForDmgr.zip` file into the installation root directory of the Deployment Manager; for example in the `/opt/IBM/WebSphere/AppServer` directory. **Note:** If the Deployment Manager profile was not created in the default `AppServer/profiles/Dmgr01` directory, then the `metadata_wkplc.xml` file, located in the `AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml` directory in the zip file, must be placed into the correct Deployment Manager profile directory.

4. If the Deployment Manager profile is running on the same application server where WebSphere Portal is installed, remove the `com.ibm.ws.portletcontainer.deploytask_6.1.5.jar` file from the `AppServer/plugins` directory.

5. Start the deployment manager.

**Parent topic:** Preparing the primary node on HP-UX  
**Previous topic:** Configure WebSphere Portal to use a remote database  
**Next topic:** Removing search collections on HP-UX

**Related tasks**
- Configuring Portal Search in a cluster on AIX
Removing search collections on HP-UX

If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Prerequisites**
- Installing WebSphere Portal on HP-UX on the primary node
- Configure WebSphere Portal to use a remote database
- Configuring the primary node to communicate with the deployment manager on HP-UX

Perform the following step to remove the search collection:

Perform the following steps to delete all existing search collections from the primary node:

1. Log on to WebSphere Portal.
2. Navigate to Administration > Search Administration > Manage Search and then click Search Collections.
3. Click the Delete Collection icon for each search collection and then click OK until they are all deleted.
4. Restart the WebSphere_Portal server and then navigate back to the Search Collections page to verify that all search collections have been deleted.

Parent topic: Preparing the primary node on HP-UX

Previous topic: Configuring the primary node to communicate with the deployment manager on HP-UX
Choosing the type of cluster to create on HP-UX

If you installed a IBM® WebSphere® Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX

Choose one of the following options to create a cluster:

- **Creating a static cluster on HP-UX**
  After installing IBM WebSphere Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

- **Creating a new dynamic cluster on HP-UX using WebSphere Virtual Enterprise**
  After installing and configuring IBM WebSphere Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

**Parent topic:** Setting up a cluster on HP-UX  
**Previous topic:** Preparing the primary node on HP-UX  
**Next topic:** Preparing a remote Web server when portal is installed on HP-UX
Creating a static cluster on HP-UX

After installing IBM® WebSphere® Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

Perform the following steps to create the cluster:

1. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   
   **Important:** Ensure that you set WasUserid and WasPassword to the Deployment Manager user ID and password.

2. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   
   **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   
   A. Set WasSoapPort to the port used to connect remotely to the deployment manager.
   B. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
   C. Verify that WasPassword is set to your deployment manager password.
   D. Verify that PortalAdminPwd is set to your WebSphere Portal password.
   E. Verify that ClusterName is set.
   F. Verify that PrimaryNode is set to true.

3. Make a backup copy of the wp_profile_root/config/cells/cell_name/wim/config/wimconfig.xml and wp_profile_root/config/cells/cell_name/wim/model/wimxmlextension.xml, if available, files.

4. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.
   
   **Note:** If you want to specify custom ports for the nodeagent, add the -DPortPropsFile=full to portsfile parameter to the cluster-node-config-pre-federation task. You can use the ports files that are found on the Setup CD for WebSphere_Portal and server1 as a guide.

   **Note:** You may receive a message about accepting an SSL signer certificate. Failure to accept the SSL signer certificate will cause the script to fail. Alternatively, the com.ibm.ssl.enableSignerExchangePrompt flag can be enabled in the ssl.client.props file for "DefaultSSLSettings" in order to allow acceptance of the signer during the connection attempt.

   **Warning:** If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:
   
   A. Remove the node if the AddNode task succeeded.
   B. Log on to the deployment manager and perform the following steps if the items exist:
      1. Remove all enterprise applications.
      2. Remove the WebSphere_Portal server definition.
      3. Remove the WebSphere Portal JDBC Provider.

   **Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following technote: Migrating with Lookaside Data.
5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la DbType` if using a property extension database in the `wkplc.properties` file.

**Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db DbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DvmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

**Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `Db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

6. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the `wp-change-portal-admin-user task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task.

8. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:

- Configuring a Web server and an application server on separate machines (remote)
- Configuring a Web server and an application server profile on the same machine
- Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard.

9. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.
B. Select Environment > WebSphere Variables.

C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.

D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.

G. Log off of the deployment manager administrative console.

11. Run the following tasks to propagate your changes: Note: WebSphere_Portal_nodename is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the serverstatus -all task to get a list of the server names and their status.

   A. ./stopManager.sh -username admin_userid -password admin_password, from the dmgr_profile_root/bin directory

   B. ./stopNode.sh -username admin_userid -password admin_password, from the wp_profile_root/bin directory

   C. ./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password

   D. ./startManager.sh, from the dmgr_profile_root/bin directory

   E. ./startNode.sh, from the wp_profile_root/bin directory

   F. ./startServer.sh WebSphere_Portal_nodename

12. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>

**Related tasks**

- Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Creating a new dynamic cluster on HP-UX using WebSphere Virtual Enterprise

After installing and configuring IBM® WebSphere® Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

Before creating your dynamic cluster, install and configure the Deployment Manager and perform all the tasks under “Preparing the primary node.” On the Deployment Manager system, install WebSphere Virtual Enterprise and augment the deployment manager profile. On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- Prerequisites
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
  - Augmenting profiles

Perform the following steps to create a dynamic cluster:

1. Perform the following steps for on the primary node of the dynamic cluster:
   A. Prepare the node for the dynamic cluster; perform all tasks under Preparing the primary node.
   B. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   C. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
      1. Set WasSoapPort to the port used to connect remotely to the deployment manager.
      2. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
      3. Verify that WasPassword is set to your deployment manager password.
      4. Verify that PortalAdminPwd is set to your WebSphere Portal password.
      5. Verify that ClusterName is set.
      6. Verify that PrimaryNode is set to true.
   D. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.

   Warning: If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:
   1. Remove the node if the AddNode task succeeded.
   2. Log on to the deployment manager and perform the following steps if the items exist:
      A. Remove all enterprise applications.
      B. Remove the WebSphere_Portal server definition.
      C. Remove the WebSphere Portal JDBC Provider.

   Note: If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following
technote: Migrating with Lookaside Data.

E. Run the following task. Include each node name as a comma separated list in the command:

1. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file. **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db DbType` to the same value that is in the `wkplc.properties` file on the primary node.

2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDomain=la federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=localhost full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

F. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

G. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-dynamic-cluster-setup` task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

2. Log on to the deployment manager administrative console.

3. Perform the following steps to create a node group:
   
   A. Click **System administration > Node groups.**
   B. Click **New.**
   C. Type the node group **Name.**
   D. Optional: Type any information about the node group in the **Description** text box.
   E. Click **OK.**
   F. Click the **Save** link to save your changes to the master configuration.

4. Perform the following steps to add members to the node group:
   
   A. Click **System administration > Node groups.**
   B. Click on the name of the node group that you want to add members to.
   C. Click **Node group members** under Additional Properties.
   D. Click **Add.**
   E. Select the primary node and then click **Add.**
   F. Click the **Save** link to save your changes to the master configuration.

5. Perform the following steps to create a dynamic cluster in the node group:
   
   A. Click **Servers > Dynamic clusters.**
   B. Click **New.**
C. Select WebSphere Application Server from the Server Type pull-down menu and then click Next.

D. Type the cluster name in the Dynamic cluster name text box and then click Next. Type the same value that you provided for the ClusterName parameter in the wkplc.properties file of your primary node.

E. Remove all default membership policies and then click Subexpression builder.

F. Enter the following information in the Subexpression builder window:

1. Select and from the Logical operator pull-down menu.
2. Select Nodegroup from the Select operand pull-down menu.
3. Select Equals (=) from the Operator pull-down menu.
4. Type the nodegroup name you created in the previous step in the Value text box.
5. Click Generate subexpression.
6. Click Append.

G. Click Preview membership to verify that all nodes included in the nodegroup display and then click Next.

H. Click the Create the cluster member using an existing server as a template radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu.

I. Click Next.

J. Specify the dynamic cluster properties and then click Next.

K. Review the summary page to verify your actions and then click Finish.

L. Click the Save link to save your changes to the master configuration.

6. Define or verify the following parameters in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:

A. Set ClusterName to the name of the new dynamic cluster.
B. Verify that CellName is set to the deployment manager cell.
C. Verify that NodeName is set to the local WebSphere Portal node.
D. Set ServerName to the server that will be used for the dynamic cluster member on this node.

   Note: Log on to the deployment manager administrative console and click Dynamic Clusters > PortalCluster > Dynamic cluster members to find the name of the server used for the dynamic cluster.

E. Verify that PrimaryNode is set to true.

7. Run the ./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the dynamic cluster.

   Note: This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

8. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.

B. Select Environment > WebSphere Variables.

C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.

D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:

   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.

G. Log off of the deployment manager administrative console.

9. Run the following tasks to propagate your changes:

   Note: WebSphere_Portal_nodename is the name of the node's WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the
server name, run the `serverstatus -all` task to get a list of the server names and their status.

A. `./stopManager.sh -username admin_userid -password admin_password`, from the `dmgr_profile_root/bin` directory

B. `./stopNode.sh -username admin_userid -password admin_password`, from the `wp_profile_root/bin` directory

C. `./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`

D. `./startManager.sh`, from the `dmgr_profile_root/bin` directory

E. `./startNode.sh`, from the `wp_profile_root/bin` directory

F. `./startServer.sh WebSphere_Portal_nodename`

**Parent topic:** Choosing the type of cluster to create on HP-UX
Preparing a remote Web server when portal is installed on HP-UX

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on HP-UX
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `on`; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server documentation</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>See the appropriate Apache Server documentation</td>
<td>AllowEncodedSlashes directives</td>
</tr>
</tbody>
</table>

4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

- **If using WebDAV:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

  **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.

**Parent topic:** Preparing prerequisite and corequisite software on HP-UX

**Previous topic:** Preparing the WebSphere Application Server Deployment Manager on HP-UX

**Parent topic:** Setting up a cluster on HP-UX

**Previous topic:** Choosing the type of cluster to create on HP-UX
Next topic: Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment
Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX

Perform the following tasks to configure WebSphere Portal to use a user registry:

- **Preparing user registries on HP-UX**
  Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

- **Choosing your user registry model on HP-UX in a clustered environment**
  Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Parent topic: Setting up a cluster on HP-UX

Previous topic: Preparing a remote Web server when portal is installed on HP-UX

Next topic: Preparing additional nodes on HP-UX
Preparing user registries on HP-UX

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

Choose the appropriate LDAP server to install and setup:

- **Preparing a Domino Directory server**
  If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a SecureWay Security Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Novell eDirectory**
  If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Sun Java System Directory Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Tivoli Directory Server**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

**Parent topic:** Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment
Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Domino Directory:

1. Perform the following steps to install the Domino Directory:
   A. Go to Lotus Domino documentation.
   B. Select the appropriate version tab for your product.
   C. Click the Download/View online link for the Lotus Domino for multiple platforms Information Center.
   D. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > Server installation > Installing Domino on Unix and perform this task.
   E. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > The Domino server setup program and perform this task.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Navigate to the People view of the Domino Directory and then click Add Person.
   B. Enter the following values in the New Person form to create the wpsbind user:
      - Last Name
        - wpsbind
      - User Name
        - wpsbind/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
      - wpsbind
        Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsbind
      - Internet password
        - wpsbind

   C. Click Save and Close to save the new person record for wpsbind and return to the People view.
   D. Click Add Person and enter the following values in the New Person form to create the wpsadmin user:
      - Last Name
        - wpsadmin, where wpsadmin in the user ID for the WebSphere Portal Administrator
      - User Name
        - wpsadmin/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
      - wpsadmin
        Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsadmin
      - Internet password
        - wpsadmin

   E. Click Save and Close to save the new person record for wpsadmin and return to the People view.
   F. Navigate to the Groups view and click Add Group.
   G. Enter the following values in the New Group form on the Basic tab.
      - Group name
- **wpsadmins**
  
  **Note:** If you plan to configure WebSphere Portal for multiple user registries and your Lotus Domino LDAP will share a realm with another user registry, you must use the hierarchical naming convention for the group names, for example: wpsadmins/DominoDomain, to avoid unexpected results during WebSphere Portal runtime.

  **- Group type**
  
  - Multi-purpose

  **- Members**
  
  - wpsbind/DominoDomain
  - wpsadmin/DominoDomain
  
  **Note:** You can add additional administrator users if required.

**H.** Click **Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

3. Perform the following steps to update the access control list for the Domino Directory:

   **A.** Open the `names.nsf` file in the Lotus Domino Administrator or Lotus Notes client.

   **B.** Click **File > Application > Access Control** from the main menu to open the access control list for the file.

   **C.** In the **Access Control List > Basics** panel, ensure that the wpsadmins group has either Author or Editor access.

   **D.** Add the following Role Types to the wpsadmins group:

   - GroupCreator
   - GroupModifier
   - UserCreator
   - UserModifier

   **E.** Click **OK**.

**Parent topic:** Preparing user registries on HP-UX
Preparing a SecureWay Security Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on HP-UX
Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Novell eDirectory:

1. Install Novell eDirectory; refer to eDirectory for information.

2. Perform the following steps to create the WebSphere Portal administrative user:

   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every dc=yourco,dc=com with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupName.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.
Preparing a Sun Java System Directory Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.

2. Perform the following steps to create the WebSphere Portal administrative user:

   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every dc=yourco,dc=com with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on HP-UX
Preparing a Tivoli Directory Server

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

   **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:

   A. Optional: Perform the following steps to create a new directory suffix:

      1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
      2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4. Click **Add**.
      5. Click **OK** to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:

      - Use the **PortalUsers.ldap** file as a working example and adapted appropriately to work with your LDAP server.
      - Use the **ContentUsers.ldap** file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every `dc=yourco,dc=com` with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to **accessGroup**. If using Tivoli Access Manager Version 6, set the **objectclasses** to **groupOfNames**.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on HP-UX
Choosing your user registry model on HP-UX in a clustered environment

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on HP-UX in a clustered environment**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

- **Adapting the attribute configuration**
  After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

**Parent topic:** Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment
Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on HP-UX in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on HP-UX in a clustered environment
Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the wp-modify-ldap-security task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the standalone.ldap.realm parameter or you can set ignoreDuplicateIds=true in the wkplc.properties file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Stand-alone LDAP configuration heading:

- standalone.ldap.id
- standalone.ldap.host
- standalone.ldap.port
- standalone.ldap.bindDN
- standalone.ldap.bindPassword
- standalone.ldap.ldapServerType
- standalone.ldap.userIdMap
- standalone.ldap.groupIdMap
- standalone.ldap.groupMemberIdMap
- standalone.ldap.userFilter
- standalone.ldap.groupFilter
- standalone.ldap.serverId
- standalone.ldap.serverPassword
- standalone.ldap.realm
- standalone.ldap.primaryAdminId
- standalone.ldap.primaryAdminPassword
- standalone.ldap.primaryPortalAdminId
- standalone.ldap.primaryPortalAdminPassword
- standalone.ldap.primaryPortalAdminGroup
- standalone.ldap.baseDN
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.et.group.objectClasses`
   - `standalone.idap.et.group.objectClassesForCreate`
   - `standalone.idap.et.group.searchBases`
   - `standalone.idap.et.personaccount.objectClasses`
   - `standalone.idap.et.personaccount.objectClassesForCreate`
   - `standalone.idap.et.personaccount.searchBases`

4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.gm.groupMemberName`
   - `standalone.idap.gm.objectClass`
   - `standalone.idap.gm.scope`
   - `standalone.idap.gm.dummyMember`

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.personAccountParent`
   - `standalone.idap.groupParent`
   - `standalone.idap.personAccountRdnProperties`
   - `standalone.idap.groupRdnProperties`

6. Save your changes to the `wkplc.properties` file.

7. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. **Note:** See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.
   - `WcmContentAuthorsGroupId`
   - `WcmContentAuthorsGroupCN`

8. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry. **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now? Press y then Enter.

9. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root` /ConfigEngine directory, to set the stand-alone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root` /ConfigEngine directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.idp.realm</code> in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the wkplc.properties file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Configuring a stand-alone LDAP user registry over SSL on HP-UX in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL: **Note:** Use the **wp_security_xxx.properties** helper file, located in the **wp_profile_root/ConfigEngine/config/helpers** directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the **wkplc.properties** file, you will use your **wp_security_xxx.properties** helper file.

1. To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to **Security > SSL certificate and key management > SSL configurations**.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: **NodeDefaultSSLSettings**
           - Clustered environments: **CellDefaultSSLSettings**
        4. **Clustered environments:** Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.
        5. Click **Key stores and certificates**.
        6. Click **Signer certificates**, click **Add**, and then enter the following information:
           - Type the **Alias** the key store uses for the signer certificate.
           - Type the **File name** where the signer certificate is located.
        7. Click **OK** and then click **Save** to save the changes to the master configuration.
   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
      2. Navigate to **Security > SSL certificate and key management > SSL configurations**.
      3. Click the appropriate SSL configuration from the list. For example,
         - Stand-alone environments: **NodeDefaultSSLSettings**
- Clustered environments: **CellDefaultSSLSettings**

**Clustered environments:** Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

- **Client trust store**
  - **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

A. See **Secure installation for client signer retrieval**.

B. Run the **retrieveSigners** task from the **wp_profile_root/bin** directory; see **retrieveSigners command** for information. In a deployed environment, you will need to run the **retrieveSigners** task, for any federated node, against the Deployment Manager. **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

1. Use a text editor to open the **ssl.client.props** file, located in the **wp_profile_root/properties** directory.

2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter **com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12** to use the default trust store.

3. Save your changes.

2. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory.

3. Required: Enter a value for the following required parameters in the **wkplc.properties** file under the VMM Standalone LDAP configuration heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - **standalone.idap.id**
   - **standalone.idap.host**
   - **standalone.idap.port**
   - **standalone.idap.blndDN**
   - **standalone.idap.bindPassword**
   - **standalone.idap.idapServerType**
   - **standalone.idap.useridMap**
   - **standalone.idap.groupldMap**
   - **standalone.idap.groupMemberldMap**
   - **standalone.idap.userFilter**
   - **standalone.idap.groupFilter**
   - **standalone.idap.serverld**
   - **standalone.idap.serverPassword**
   - **standalone.idap.realm**
   - **standalone.idap.primaryAdminId**
   - **standalone.idap.primaryAdminPassword**
   - **standalone.idap.primaryPortalAdminId**
4. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading:\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- `standalone.ldap.et.group.objectClasses`
- `standalone.ldap.et.group.objectClassesForCreate`
- `standalone.ldap.et.group.searchBases`
- `standalone.ldap.et.personaccount.objectClasses`
- `standalone.ldap.et.personaccount.objectClassesForCreate`
- `standalone.ldap.et.personaccount.searchBases`

5. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading: \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- `standalone.ldap.gm.groupMemberName`
- `standalone.ldap.gm.objectClass`
- `standalone.ldap.gm.scope`
- `standalone.ldap.gm.dummyMember`

6. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading: \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- `standalone.ldap.personAccountParent`
- `standalone.ldap.groupParent`
- `standalone.ldap.personAccountRdnProperties`
- `standalone.ldap.groupRdnProperties`

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL): \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

Required parameters:

- `standalone.ldap.sslEnabled`
- `standalone.ldap.sslConfiguration`

Optional parameters:

- `standalone.ldap.certificateMapMode`
- `standalone.ldap.certificateFilter`

8. Save your changes to the `wkplc.properties` file.

9. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. \textbf{Attention:} If you have not deleted the default file repository, \textbf{WasPassword} is the value entered during installation and not a value found in your LDAP user registry.

\textbf{Note:} During the validation task, you may receive the following prompt: \textit{Add signer to the trust store now?}. Press `y` then \textbf{Enter}.

10. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the \textit{wp_profile_root}/ConfigEngine directory, to set the stand-alone LDAP user registry.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: \textit{Starting and stopping servers, deployment managers, and node agents}.

12. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the \textit{wp_profile_root}/ConfigEngine directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on HP-UX in a clustered environment

**Related tasks**

- Enabling LDAP security after cluster creation
Configuring the default federated repository on HP-UX in a clustered environment

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on HP-UX in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on HP-UX in a clustered environment**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on HP-UX in a clustered environment**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Parent topic: Choosing your user registry model on HP-UX in a clustered environment
Configuring a federated LDAP user registry on HP-UX in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Adding an LDAP user registry on HP-UX in a clustered environment**
  
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName,o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

- **Adding an LDAP user registry over SSL on HP-UX in a clustered environment**
  
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

**Parent topic:** Configuring the default federated repository on HP-UX in a clustered environment
Adding an LDAP user registry on HP-UX in a clustered environment

Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM® Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName,o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as wpsadmin, this ID cannot exist in the LDAP you are adding.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `federated.ldap.id`
   - `federated.ldap.host`
   - `federated.ldap.port`
   - `federated.ldap.bindDN`
   - `federated.ldap.bindPassword`
   - `federated.ldap.ldapServerType`
   - `federated.ldap.baseDN`
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `federated.ldap.et.group.objectClasses`
   - `federated.ldap.et.group.objectClassesForCreate`
   - `federated.ldap.et.group.searchBases`
   - `federated.ldap.et.personaccount.objectClasses`
4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attribute heading: 

```
- federated.ldap.et.personaccount.objectClassesForCreate
- federated.ldap.et.personaccount.searchBases
```

Note: See the properties file for specific information about the required parameters and for advanced parameters.

```
- federated.ldap.gm.groupMemberName
- federated.ldap.gm.objectClass
- federated.ldap.gm.scope
- federated.ldap.gm.dummyMember
```

5. Save your changes to the `wkplc.properties` file.

6. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. 

Note: See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.

```
- WcmContentAuthorsGroupId
- WcmContentAuthorsGroupCN
```

7. Run the `./ConfigEngine.sh validate-federated-ldap -DWasPassword=password` task to validate your LDAP server settings. 

Attention: If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.

Note: During the validation task, you may receive the following prompt: Add signer to the trust store now? . Press y then Enter.

8. Run the `./ConfigEngine.sh wp-create-ldap -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add an LDAP user registry to the default federated repository. 

Note: Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms: 

Note: See the properties file for specific information about the required parameters and for advanced parameters.

```
- id
- baseDN
- nameInRepository
```

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

11. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

12. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

13. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

   A. Edit the `wp_profile_root/PortalServer/wcm/shared/app/config/wcm/services/MemberFixerModule.properties` file.

   B. Add the following lines to the file:

   ```
   uid=xyzadmin, o=defaultWIMFileBasedRealm -> portal_admin_DN
   cn=contentauthors, o=defaultWIMFileBasedRealm -> content_authors_group_DN
   ```
Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management.

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

16. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

17. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   **Important:**
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

   **Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

   A. Run the following task from the `wp_profile_root/ConfigEngine` directory: `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.

   B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

   C. Run the following task from the `wp_profile_root/ConfigEngine` directory: `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
18. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a federated LDAP user registry on HP-UX in a clustered environment

Adding an LDAP user registry over SSL on HP-UX in a clustered environment

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

Tip: Perform these steps on the primary node only.

Note: Use the wp_add_federated_xxx.properties helper file, located in the wp_profile_root /ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_add_federated_xxx.properties helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: NodeDefaultSSLSettings
           - Clustered environments: CellDefaultSSLSettings

        **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
        4. Click Key stores and certificates.
        5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
        6. Click Signer certificates, click Add, and then enter the following information:
           - Type the Alias the key store uses for the signer certificate.
           - Type the File name where the signer certificate is located.
        7. Click OK and then click Save to save the changes to the master configuration.
     B. Retrieve the certificate from the port:
        1. Log in to the WebSphere Application Server Administrative Console.
2. Navigate to **Security > SSL certificate and key management > SSL configurations**.

3. Click the appropriate SSL configuration from the list. For example,
   - Stand-alone environments: **NodeDefaultSSLSettings**
   - Clustered environments: **CellDefaultSSLSettings**

   **Clustered environments:** Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

   **Client trust storeNote:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

   A. See **Secure installation for client signer retrieval**.

   B. Run the **retrieveSigners** task from the **wp_profile_root/bin** directory; see **retrieveSigners command** for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

   1. Use a text editor to open the **ssl.client.props** file, located in the **wp_profile_root/properties** directory.
   2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter

   ```
   com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12
   ```

   to use the default trust store.
   3. Save your changes.

2. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory.

3. Required: Enter a value for the following required parameters in the **wkplc.properties** file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - **federated.idap.id**
   - **federated.idap.host**
   - **federated.idap.port**
   - **federated.idap.blndDN**
   - **federated.idap.blndPassword**
   - **federated.idap.idapServerType**
   - **federated.idap.baseDN**

4. Required: Enter a value for the following required entity types parameters in the **wkplc.properties** file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - **federated.idap.et.group.objectClasses**
   - **federated.idap.et.group.objectClassesForCreate**
   - **federated.idap.et.group.searchBases**
5. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attribute heading: 

- federated.ldap.gm.groupMemberName
- federated.ldap.gm.objectClass
- federated.ldap.gm.scope
- federated.ldap.gm.dummyMember

Note: See the properties file for specific information about the required parameters and for advanced parameters.

6. Enter a value for the following parameters to enable Secure Socket Layers (SSL):

- federated.ldap.sslEnabled
- federated.ldap.sslConfiguration

Optional parameters:

- federated.ldap.certificateMapMode
- federated.ldap.certificateFilter

7. Save your changes to the wkplc.properties file.

8. Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. 

- WcmContentAuthorsGroupId
- WcmContentAuthorsGroupCN

Note: See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.

9. Run the .//ConfigEngine.sh validate-federated-ldap -DWasPassword=Password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry.

Note: During the validation task, you may receive the following prompt: Add signer to the trust store now? Press y then Enter.

10. Run the .//ConfigEngine.sh wp-create-ldap -DWasPassword=Password task, from the wp_profile_root/ConfigEngine directory, to add an LDAP user registry to the default federated repository. Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

12. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

B. Enter a value for the following required parameters in the wkplc.properties file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms.

Note: See the properties file for specific information about the required parameters and for advanced parameters.
- Id
- baseDN
- nameInRepository

C. Save your changes to the wkplc.properties file.

D. Run the `./ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

14. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

15. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:
      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:
      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

      C. Save your changes to the `wkplc.properties` file.

      D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

      E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.
E. Stop and restart all necessary servers to propagate your changes.

17. Configure your Web server over SSL. Navigate to Configuring WebSphere Portal > Additional security features > Configuring SSL > Setting up SSL for information.

18. Log on to the WebSphere Application Server Administrative Console and navigate to Security > SSL certificate and key management. Click the Use the United States Federal Information Processing Standard (FIPS) algorithms. check box to enable FIPS.

19. Enable TLS in your internet browser, located under Tools > Options > Advanced.

20. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   Note: This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the configure-express task.

   A. Edit the wp_profile_root
   /PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

   B. Add the following lines to the file:

   ```
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
   cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
   ```

   Replace portal_admin_DN with the distinguished name of the portal administrator and content_authors_group_DN with the distinguished name of the content authors group used during LDAP configuration.

   C. Save your changes and close the file.

   D. Run the "./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password" task, located in the wp_profile_root/ConfigEngine directory. Note: Choose the appropriate value to enter for realm_name depending on the type of LDAP user registry you configured: Table 1. Value for realm_name when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for realm_name should match the value for standalone.ldap.realm in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for realm_name should match the value for federated.realm in the wkplc.properties file. If the value for federated.realm is empty, use defaultWIMFileBasedRealm as the default value.</td>
</tr>
</tbody>
</table>

21. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

22. Optional: This step is required in a production environment. Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   Important:
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.
**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root/ConfigEngine` directory:

```
./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword
```

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.

B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine` directory:

```
./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid
```

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

23. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a federated LDAP user registry on HP-UX in a clustered environment

- User IDs and passwords
Adding a database user registry on HP-UX in a clustered environment

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you have WebSphere Application Server Version 7.0.x installed, you must install APAR PM23090 and APAR PM24181 for WebSphere Portal prior to running this task. Clusters with WebSphere Application Server Version 6.1.x do not require these APARs.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_DB.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_DB.properties` helper file.

1. Set up a new database, including creating a new user with appropriate database privileges for accessing the database:

   **Instructions for setting up databases:** Refer to the appropriate documentation for the type of database you want to set up.

   **Consulting your database administrator:** The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

   **Table 1. Steps for creating a new database to use as a database user registry.**

<table>
<thead>
<tr>
<th>Database</th>
<th>Steps</th>
</tr>
</thead>
</table>

1441
<table>
<thead>
<tr>
<th>Database Type</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB2</strong></td>
<td>Perform the following steps to create a DB2 database: Install DB2. Enter the following database tuning commands: db2 &quot;CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192&quot; db2 &quot;UPDATE DB CFG FOR dbname USING appheapsz 4096&quot; db2 &quot;UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024&quot; db2 &quot;UPDATE DB CFG FOR dbname USING stmtheap size 32768&quot; db2 &quot;UPDATE DB CFG FOR dbname USING dbheap 1400&quot; db2 &quot;UPDATE DB CFG FOR dbname USING locklist 1000&quot; db2 &quot;UPDATE DB CFG FOR dbname USING logfilsiz 4000&quot; db2 &quot;UPDATE DB CFG FOR dbname USING logprimary 12&quot; db2 &quot;UPDATE DB CFG FOR dbname USING logsecond 20&quot; db2 &quot;UPDATE DB CFG FOR dbname USING avg_appls 5&quot; db2 &quot;UPDATE DB CFG FOR dbname USING locktimeout 30&quot; db2 &quot;UPDATE DB CFG FOR dbname USING AUTO_MAINT off&quot;</td>
</tr>
<tr>
<td><strong>Oracle</strong></td>
<td>Perform the following steps to create an Oracle database: Install Oracle using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16. Configure the database in Dedicated Server Mode. Enter the recommended initial buffer pool sizes or set them according to your business needs: <code>db_block_size = 8192</code>, <code>db_cache_size = 300M</code>, <code>db_files = 1024</code>, <code>log_buffer = 65536</code>, <code>open_cursors = 1500</code>, <code>pga_aggregate_target = 200M</code>, <code>pre_page_sga = true</code>, <code>processes = 300</code>, <code>shared_pool_size = 200M</code></td>
</tr>
<tr>
<td><strong>SQL Server</strong></td>
<td>Perform the following steps to create an SQL Server database: Install SQL Server. Set <strong>Collation</strong> to <strong>case-sensitive</strong>. <strong>Note:</strong> Install SQL Server with the appropriate portal database collation so that your tempdb collation setting matches the collation you use for the property extension database. The tempdb collation is inherited from the master database, which you set when you install SQL Server.</td>
</tr>
</tbody>
</table>

2. Perform the following steps to define the **DbDriver** and **DbLibrary** parameter values:
   A. Navigate to the following directory: `wp_profile_root/ConfigEngine/properties`  
   B. Locate and open `wkplc_dbtype.properties` with any text editor.  
   C. Enter a value for the following parameters under the appropriate database type properties heading:  
      - `db_type.DbDriver`  
      - `db_type.DbLibrary`  
   D. Save your changes.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated Database Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
5. Change the value for the \texttt{com.ibm.SOAP.requestTimeout} parameter to 1000.
   A. Navigate to the following directory: \texttt{wp_profile_root/properties}
   B. Locate and open \texttt{soap.client.props} with any text editor.
   C. Locate the \texttt{com.ibm.SOAP.requestTimeout} parameter and change the value to 1000.
   D. Save and close \texttt{soap.client.props}.

6. Perform the following steps in a clustered environment:
   A. Run the \texttt{/ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=\textit{password} -DDbDomain=federated.db -D\texttt{db_type}.DmgrDbLibrary=\textit{local path of the database jars on the Deployment Manager} -DDmgrnodeName=\textit{dmgr_node_name}} task from the \texttt{wp_profile_root/ConfigEngine} directory to create the local Deployment Manager WebSphere variable used to access the database jars. \textbf{Note:} The \texttt{db_type} in \texttt{db_type}.\texttt{DmgrDbLibrary} should be set to the type of database you are using, for example \texttt{db2}. The \texttt{local full path of the database jars on the Deployment Manager} should be one of the following options:
      - \texttt{DB2 Type 2 driver:db2java.zip}
      - \texttt{DB2 Type 4 driver:db2jcc.jar;db2jcc_license_cu.jar}
      - \texttt{DB2 for z/OS Type 2 driver:db2java.zip}
      - \texttt{DB2 for z/OS Type 4 driver:db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc javax.jar}
      - \texttt{Oracle:ojdbc14.jar}
      - \texttt{SQL Server JDBC driver provided by Microsoft:sqljdbc.jar}
      - \texttt{SQL Server JDBC driver provided by DataDirect:sqlserver.jar;base.jar;util.jar}
   B. Run the following task. Include each node name as a comma separated list in the command:
      \textbf{Running the task:} You do not have to run this task more than once. You can run this task from any node in the cluster.
      1. Set the property value for \texttt{federated.dbDbType} in the \texttt{wkplc.properties} file if using a database user registry.
      2. Run the \texttt{/ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=\textit{password} -DDbDomain=federated.db -DVmmNodeName=\textit{node_name} -D\texttt{db_type}.NodeDbLibrary=\textit{local full path of the database jars}} task from the \texttt{wp_profile_root/ConfigEngine} directory on each node to create the variable used to access the VMM database jars. \textbf{Note:} The \texttt{VmmNodeName} is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The \texttt{db_type} in \texttt{db_type}.\texttt{NodeDbLibrary} should be set to the type of database you are using, for example \texttt{db2}.
   C. Stop and restart all necessary servers to propagate your changes.

7. Run the \texttt{/ConfigEngine.sh wp-create-db -DWasPassword=\textit{password}} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to add a database user registry to the default federated repository. \textbf{Note:} Users who are not in an LDAP do
8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `. /ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the `. /ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

    If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring the default federated repository on HP-UX in a clustered environment

Enabling LDAP security after cluster creation
Adding realm support on HP-UX in a clustered environment

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM realm configuration heading:
   - `realmName`
   - `securityUse`
   - `delimiter`
   - `addBaseEntry`
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
3. Save your changes to the `wkplc.properties` file.
4. Run the `./ConfigEngine.sh wp-create-realm -DWasPassword=[password] task`, from the `wp_profile_root/ConfigEngine` directory, to add a new realm to the Virtual Member Manager configuration. Important: To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the `wkplc.properties` file with the base entry information and rerun the `wp-create-realm` task. Repeat these steps until all realms are created.
5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.
6. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM realm configuration heading and then save your changes:
   - `realmName`
   - `realm.personAccountParent`
   - `realm.groupParent`
   - `realm.orgContainerParent`
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
7. Run the `./ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=[password]` task, from the `wp_profile_root/ConfigEngine` directory, to update the default parents per entity type and realm. Important: Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types.
and realms.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:

A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:

   - realmName
   - addBaseEntry

C. Save your changes to the wkplc.properties file.

D. Run the ./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=password task, from the wp_profile_root /ConfigEngine directory, to add additional LDAP base entries to the realm configuration.

E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:

A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.

B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.

C. Create a new group in the Manage Users and Groups portlet to replace the current group.

D. Run the ./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminId -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task, from the wp_profile_root/ConfigEngine directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.

E. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

F. Run the ./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminId -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task to replace the old WebSphere Portal administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.

G. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

11. Optional: Perform the following steps to set the realm you created as the default realm: **Remember:** Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the wp-query-realm-baseentry task to see what base entries are part of the default realm. If the default realm is missing
the base entry, run the wp-add-realm-baseentry task to add the base entry to the default realm.

A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

B. For defaultRealmName, type the realmName property value you want to use as the default realm.

C. Save your changes to the wkplc.properties file.

D. Run the./ConfigEngine.sh wp-default-realm -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to set this realm as the default realm.

E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:

   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

   B. For realmName, type the name of the realm you want to query.

   C. Save your changes to the wkplc.properties file.

   D. Run the ./ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

   B. Enter a value for realmName or leave blank to update the default realm.

   C. Save your changes to the wkplc.properties file.

   D. Run the ./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password task, located in the wp_profile_root/ConfigEngine directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the ./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the enable-jcr-security task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

Adapting the attribute configuration

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. **Querying the defined attributes on HP-UX**
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. **Adding attributes on HP-UX in a clustered environment**
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. **Mapping attributes on HP-UX in a clustered environment**
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. **Removing attributes**
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

**Parent topic:** Choosing your user registry model on HP-UX in a clustered environment

**Related tasks**

- Adding an LDAP user registry on HP-UX

- Configuring a stand-alone LDAP user registry on HP-UX
Configuring a stand-alone LDAP user registry over SSL on HP-UX
Querying the defined attributes on HP-UX

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `./ConfigEngine.sh wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (**PersonAccount**) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on HP-UX in a clustered environment
Adding attributes on HP-UX in a clustered environment

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone environment</td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the \wp_profile_root\ConfigEngine directory. Run the ./ConfigEngine.sh wp-la-install-ear -DWasPassword=password task.</td>
</tr>
<tr>
<td>Clustered environment</td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the \wp_profile_root\ConfigEngine directory on the primary node. Run the ./ConfigEngine.sh wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name task. Where node_name is the name of the node where the deployment manager resides; you can find the node_name value in the WebSphere Application Server Administrative Console under System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

3. Use a text editor to open the wkplc.properties file, located in the \wp_profile_root\ConfigEngine\properties directory.

4. Enter a value for the following required parameters in the wkplc.properties file under the VMM Property Extension Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - la.providerURL
   - la.propertyName
   - la.entityTypes
   - la.dataType
   - la.multiValued

5. Save your changes to the wkplc.properties file.
6. Run the `./ConfigEngine.sh wp-add-property -DWasPassword=password` task to add the attribute to the user registry.

   **Note:** This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

   **Remember:** If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

   If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

**Parent topic:** Adapting the attribute configuration

**Previous topic:** Querying the defined attributes on HP-UX

**Next topic:** Mapping attributes on HP-UX in a clustered environment

**Related tasks**

- Starting and stopping servers, deployment managers, and node agents

<td>federated.ldap.idfederated.ldap.hostfederated.ldap.portfederated.ldap.sslEnabledfederated.ldap.bindDNfederated.ldap.bindPasswordfederated.ldap.baseDN</td>
</tr>
</tbody>
</table>

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory.</td>
</tr>
<tr>
<td>Federated</td>
<td>./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory.</td>
</tr>
</tbody>
</table>

4. Open the ConfigTrace.log file, located in the wp_profile_root/ConfigEngine/log directory, to review the following output for the PersonAccount and Group entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the `uid`, `cn`, `firstName`, `sn`, `preferredLanguage`, and `ibm-primaryEmail` attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

6. Enter a value for one of the following sets of parameters in the `wkplc.properties` file to correct any issues found in the config trace file: Table 3. Parameters to define in the `wkplc.properties` file to correct any issues found in the config trace file.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
</table>
| Stand-alone     | The following parameters are found under the LDAP attribute configuration heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters. `standalone.id=standalone.ldap.attributes.nonSupported.standalone.ldap.attributes.nonSupported.deletestandalone.ldap.attributes.mapping.ldapName=standalone.ldap.attributes.mapping.portalName=standalone.ldap.attributes.mapping.entityTypes=PersonAccount, Group` For example, the following values will flag `certificate` and `members` as unsupported attributes and will map `ibm-primaryEmail` to `mail` and `ibm-jobTitle` to `title` for both the `PersonAccount` and `Group` entity types. `standalone.id=standalone.ldap.attributes.nonSupported=certificate, members` `standalone.id=standalone.ldap.attributes.nonSupported.delete=standalone.ldap.attributes.mapping.ldapName=mail, title` `standalone.id=standalone.ldap.attributes.mapping.portalName=ibm-primaryEmail, ibm-jobTitle` `standalone.id=standalone.ldap.attributes.mapping.entityTypes=PersonAccount, Group`
7. Save your changes to the wkplc.properties file.

8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

   Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>./ConfigEngine.sh wp-update-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory</td>
</tr>
<tr>
<td>Federated</td>
<td>./ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory</td>
</tr>
</tbody>
</table>

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:
   A. Enter a value for the following required parameters in the wkplc.properties file: Note: See the properties file for specific information about the required parameters and for advanced parameters.
      - `user.attributes.required`
      - `user.attributes.nonsupported`
   B. Save your changes to the wkplc.properties file.
   C. Run the `./ConfigEngine.sh wp-update-attribute-config -DWasPassword=password` task, from the wp_profile_root/ConfigEngine directory.
   D. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See Enabling LDAP security after cluster creation for instructions.
Related tasks
Starting and stopping servers, deployment managers, and node agents
Enabling LDAP security after cluster creation
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database:

**Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.
   A. Open the tool you use to edit your database.
   B. Verify that your attribute name is available in the LAPROP table.
   C. Delete the required attributes from the LAPROP table.
   D. Open the `wimxmlextension.xml` file, located in the `wp_profile_root/config(cells/cellname/wim/model` directory.
   E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:
      ```xml
      <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
                      multiValued="true" propertyName="attribute_name">
        <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
      </wim:propertySchema>
      ```
   F. Save your changes to the `wimxmlextension.xml` file.
   G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config(cells/cellname/wim/config` directory.
   H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:
      ```xml
      <config:propertiesNotSupported name="attribute_name">
      </config:propertiesNotSupported>
      ```
   I. Save your changes to the `wimconfig.xml` file.
   J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:
   A. Open the `wimxmlextension.xml` file.
   B. Locate and delete the `propertySchema` definition for the attributes you previously added:
      ```xml
      <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
                      multiValued="true" propertyName="attribute_name">
        <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
      </wim:propertySchema>
      ```
   C. Save your changes to the `wimxmlextension.xml` file.
   D. Open the `wimconfig.xml` file.
   E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:
      ```xml
      <config:attributes name="attribute_name" propertyName="property_name">
        <config:entityTypes>PersonAccount</config:entityTypes>
      </config:attributes>
      ```
   F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

**Parent topic:** Adapting the attribute configuration

**Previous topic:** Mapping attributes on HP-UX in a clustered environment
Preparing additional nodes on HP-UX

After installing and configuring your primary node, you can create your secondary nodes. You must install IBM® WebSphere® Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX
  - Installing a secondary node after migrating from previous version

Perform the following tasks to prepare your secondary node:

1. **Installing WebSphere Portal on HP-UX on the additional nodes**
   - Install IBM WebSphere Portal on your secondary nodes to create a highly available and scalable environment.

2. **Choosing the type of additional node to create on HP-UX**
   - If you created a static cluster using the IBM WebSphere Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

3. **Choosing the type of vertical cluster to create on HP-UX**
   - If you are using the IBM WebSphere Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

**Parent topic:** Setting up a cluster on HP-UX

**Previous topic:** Configuring WebSphere Portal to use a user registry on HP-UX in a clustered environment

**Next topic:** Tune your servers
Installing WebSphere Portal on HP-UX on the additional nodes

Install IBM® WebSphere® Portal on your secondary nodes to create a highly available and scalable environment.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. **Note:** If you plan to use IBM WebSphere Application Server Version 7.0, you must purchase and install it before installing WebSphere Portal on the existing WebSphere Application Server Version 7.0 instance.

Perform the following steps to install WebSphere Portal:

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities

3. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:
   - **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   A. Install the current supported version of WebSphere Application Server as a root user.
   B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:
      1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
      2. Run the following tasks to change the rights of the non-root user:
         ```
         chmod -R g+rwX /opt/IBM
         chgrp -R group_name /opt/IBM
         chmod -R g+wr /tmp
         chgrp -R group_name /tmp
         chmod -R g+wr /var/tmp
         ```
C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

4. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

   **Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

   **Restriction:** When defining your installation path, the **ONLY** supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Graphical user interface</strong></td>
<td>./install.sh</td>
</tr>
<tr>
<td><strong>Console mode</strong></td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td><strong>Silent Install</strong></td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. <strong>Important:</strong> Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

5. Verify your installation was successful; access WebSphere Portal using the http://yourserver:yourport/wps/portal format. Run the ./ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

6. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

   **Note:** The starting port parameter is required for a successful completion of the modify-ports-by-startport task.

   Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

A. Stop the server1 and WebSphere_Portal servers.
B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

7. To prevent Out of Memory errors, perform the following steps to set the MaxPermSize:

Tip: If Maximum Heap Size is set to 2048 M or higher, set the MaxPermSize to a quarter of the value entered for the Maximum Heap Size; for example, if your Maximum Heap Size is 3000 M, set MaxPermSize to 750 M. If your Maximum Heap Size is less than 2048 M, set MaxPermSize to 512 M.

A. Log in to the WebSphere Application Server Administration Console.

B. Click Servers > Server Types > WebSphere application servers > WebSphere_Portal.

D. In the Generic JVM arguments field, change the MaxPermSize value to -XX:MaxPermSize=numeric value, where numeric value is a quarter of the value entered for the Maximum Heap Size. Important: If MaxPermSize does not exist in the Generic JVM arguments field, add it to the field but do not replace existing information in the Generic JVM arguments field with the MaxPermSize information.

E. Click OK to save your changes.

F. Click Save to save your changes to the master configuration.

G. Log out of the WebSphere Application Server Administration Console.

H. Restart the server1 and WebSphere_Portal servers.

8. Perform the following steps if you migrated from a previous version of WebSphere Portal:

A. Log on to the WebSphere Application Server Administrative Console.

C. Click WP Identification.

D. Click Custom properties.

E. If applicable, note the location of the LpidToGupidMapping.properties file.

F. If the LpidToGupidMapping.properties file exists on the primary node, copy the file to the same location on the secondary node.

Advanced installation parameters
Choosing the type of additional node to create on HP-UX

If you created a static cluster using the IBM® WebSphere® Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

- **Prerequisites**
  - Installing WebSphere Portal on HP-UX on the additional nodes

Choose one of the following options to add additional nodes to your cluster:

- **Adding additional nodes to the static cluster on HP-UX**
  After installing IBM WebSphere Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

- **Adding an additional node to an existing dynamic cluster**
  After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM WebSphere Virtual Enterprise dynamic cluster.

**Parent topic:** Preparing additional nodes on HP-UX

**Previous topic:** Installing WebSphere Portal on HP-UX on the additional nodes

**Next topic:** Choosing the type of vertical cluster to create on HP-UX
Adding additional nodes to the static cluster on HP-UX

After installing IBM® WebSphere® Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

Perform the following steps to add the secondary node to the cluster:

1. Perform the following steps on the secondary node to access your database server: **Note:** All properties files are located in the `wp_profile_root/ConfigEngine/properties` directory.
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   C. Set all database properties in the `wkplc_dbtype.properties` and `wkplc_comp.properties` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. `./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password`
   B. `./ConfigEngine.sh validate-database-connection -DWasPassword=password -DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory of the secondary node: **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   A. Verify that `WasUserid` is set to your deployment manager administrator ID.
   B. Verify that `WasPassword` is set to your deployment manager administrator password.
   C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is 8879.
   G. Verify that `PrimaryNode` is set to `false`.
   H. Verify that `ClusterName` is set to the primary node’s `ClusterName`.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
   **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.
   A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.
   **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user...
registry or a property extension database, set the property value for `federated.dbDbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `.ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DbDomain=localhost -DVmmNodeName=node_name -DbDbType.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

**Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

6. Run the `.ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the `ServerName` parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `.ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user -DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Optional: Open the `wkplc.properties` file and change the `ServerName` parameter from the default WebSphere_Portal_nodename value to a value that meets your business needs. Do not change the parameter to WebSphere_Portal as this is the primary node value.

9. Run the `.ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task to add the node to your cluster.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.
B. Select `Environment > WebSphere Variables`.
C. From the `Scope` drop-down menu, select the `Node=nodename, Server=servername` option to narrow the scope of the listed variables, where `nodename` is the node that contains the application server.
D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

12. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

Parent topic: Choosing the type of additional node to create on HP-UX

Related tasks
Deleting passwords from properties files
Adding an additional node to an existing dynamic cluster

After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM® WebSphere® Virtual Enterprise dynamic cluster.

On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

**Prerequisites**

- PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
- Installing and configuring the product:
- Augmenting profiles

Perform the following steps to add an additional node to an existing WebSphere Virtual Enterprise dynamic cluster:

1. Perform the following steps on the secondary node to access your database server. **Note:** All properties files are located in the \wp_profile_root\ConfigEngine\properties directory.
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   C. Set all database properties in the \wkplc_dbtype.properties and \wkplc_comp.properties files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. `./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password`
   B. `./ConfigEngine.sh validate-database-connection -DWasPassword=password -DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the \wp_profile_root\ConfigEngine\properties directory of the secondary node. **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   A. Verify that **WasUserid** is set to your deployment manager administrator ID.
   B. Verify that **WasPassword** is set to your deployment manager administrator password.
   C. Verify that **PortalAdminId** is set to your WebSphere Portal administrator ID.
   D. Verify that **PortalAdminPwd** is set to your WebSphere Portal password.
   E. Verify that **WasRemoteHostName** is set to the fully qualified host name of the deployment manager.
   F. Verify that **WasSoapPort** is set to the SOAP port that the deployment manager is using; the default value is 8879.
   G. Verify that **PrimaryNode** is set to false.
H. Verify that `ClusterName` is set to the primary node’s `ClusterName`.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

   **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

   A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.

      **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

   B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

      **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

6. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the `ServerName` parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Log on to the deployment manager administrative console.

9. Perform the following steps to add members to the node group:

   A. Click `System administration > Node groups`. 
B. Click on the name of the node group that you want to add members to.
C. Click **Node group members** under Additional Properties.
D. Click **Add**.
E. Select the additional node you want to add into the node group and then click **Add**.
F. Click the **Save** link to save your changes to the master configuration.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Define or verify the following parameters in the wkplc.properties file, located in the **wp_profile_root**/ConfigEngine/properties directory:

   A. Set **ClusterName** to the name of the existing dynamic cluster.
   B. Verify that **CellName** is set to the deployment manager cell.
   C. Verify that **NodeName** is set to the local WebSphere Portal node.
   D. Set **ServerName** to the server that will be used for the dynamic cluster member on this node. **Note:** Log on to the deployment manager administrative console and click **Dynamic Clusters > PortalCluster > Dynamic cluster members** to find the name of the server used for the dynamic cluster.
   E. Verify that **PrimaryNode** is set to **false** because this is an additional node.

12. Run the ./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password task to add the new member to the existing dynamic cluster. **Note:** This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

13. Perform the following steps to start the cluster member:

   A. Log on to the Deployment Manager administrative console.
   B. Navigate to **Servers > Dynamic clusters > cluster name > Dynamic cluster members**.
   C. Select the cluster member and click **Start**.
   D. Log off of the deployment manager administrative console.

14. Perform the following steps to access the Web Content Management content through an external Web server:

   A. Log on to the deployment manager administrative console.
   B. Select **Environment > WebSphere Variables**.
   C. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server.
   D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select **System Administration > Nodes**.
      2. Select the node that you want to synchronize from the list.
      3. Click **Full Resynchronize**.
   G. Log off of the deployment manager administrative console.

15. Run the following tasks to propagate your changes. **Note:** **WebSphere_Portal_nodename** is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the **serverstatus -all** task to get a list of the server names and their status.

   A. ./stopManager.sh -username admin_userid -password admin_password, from the dmgr_profile_root\bin directory
   B. ./stopNode.sh -username admin_userid -password admin_password, from the wp_profile_root/bin directory
   C. ./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password
D. ./startManager.sh, from the dmgr_profile_root/bin directory
E. ./startNode.sh, from the wp_profile_root/bin directory
F. ./startServer.sh WebSphere_Portal_nodename

16. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Choosing the type of additional node to create on HP-UX

**Related tasks**
Deleting passwords from properties files
Choosing the type of vertical cluster to create on HP-UX

If you are using the IBM® WebSphere® Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

- **Prerequisites**
  - Installing WebSphere Portal on HP-UX on the additional nodes

Choose one of the following options to add vertical cluster members to your cluster.

- **Adding vertical cluster members to a static cluster on HP-UX**
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

- **Adding vertical cluster members to a dynamic cluster on HP-UX**
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

**Parent topic:** Preparing additional nodes on HP-UX

**Previous topic:** Choosing the type of additional node to create on HP-UX
Adding vertical cluster members to a static cluster on HP-UX

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Log into the deployment manager administrative console.
2. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - For WebSphere Application Server Version 6.1: Click Servers > Clusters in the console navigation tree, select the cluster name, and then click Cluster members from the list of additional properties.
   - For WebSphere Application Server Version 7.0: Click Servers > Clusters > WebSphere application server clusters > cluster_name > Cluster members.
   - Click New to create the cluster member.
   - Define the name of cluster member. Note: Do not use spaces in the cluster member name.
   - Select an existing node where IBM® WebSphere® Portal is installed.
   - Check the box Generate Unique HTTP Ports.
   - Click Add Member and then click Next to view the summary.
   - Important: You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.
   - Click Finish, and save the changes.
3. Perform the following steps to enable cache replication:
   - From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new server cluster members.
   - Click Dynamic cache service under Container services.
   - Change Cache size to 3000 entries.
   - Check the Enable cache replication check box.
   - Select NOT_SHARED from the Replication type drop-down menu.
   - Click OK.
   - Click Save to save your changes to the master configuration.
4. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   - Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   - Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.
7. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node-nodename, Server-servername option to narrow the scope of the listed variables, where Node-nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Resynchronize.
   G. Log off of the deployment manager administrative console.
8. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click Save on the task bar, and save your administrative configuration.
   B. Select System Administration > Nodes, select the node from the list, and click Full Resynchronize.
9. Regenerate the Web server plug-in.
   A. Regenerate the Web server plug-in using the deployment manager administrative console.
   B. If you are using a remote Web server, copy the updated plug-in configuration file (plugin-cfg.xml) to the Web server’s plug-in configuration directory.
10. Stop and start the Web server.

Parent topic: Choosing the type of vertical cluster to create on HP-UX
Adding vertical cluster members to a dynamic cluster on HP-UX

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Open a browser and enter http://DM01:9060/ibm/console in the address bar to access the administrative console on the deployment manager, where DM01 is the deployment manager node or host name. The port number might differ based on your installation.

2. Perform the following steps to allow vertical clusters on your dynamic cluster:
   A. Navigate to Servers > Dynamic clusters and select the appropriate dynamic cluster.
   B. Select the Allow more than one instance to start on the same node check box under Vertical stacking of Instances on node.
   C. Enter a new value in the Number of instances text box to determine the number of vertical cluster members allowed on each node.
   D. Click Apply and then click Save to save the changes to the master configuration.

   The new cluster topology can be viewed from the Servers > Cluster Topology view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the Servers > Clusters > Cluster Topology view.

   Important: You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.

3. Perform the following steps to enable cache replication:
   A. From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new vertical cluster member(s).
   B. Click Dynamic cache service under Container services.
   C. Change Cache size to 3000 entries.
   D. Check the Enable cache replication check box.
   E. Select NOT_SHARED from the Replication type drop-down menu.
   F. Click OK.
   G. Click Save to save your changes to the master configuration.

4. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   A. Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   B. Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.

5. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
B. Select Environment > WebSphere Variables.
C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.
G. Log off of the deployment manager administrative console.
6. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click Save on the task bar, and save your administrative configuration.
   B. Select System Administration > Nodes, select the node from the list, and click Full Resynchronize.
7. Stop and start the Web server.

Parent topic: Choosing the type of vertical cluster to create on HP-UX
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX

**Base Portal Tuning Scenarios**

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services

Configuring search in a cluster on HP-UX

IBM® WebSphere® Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

**Prerequisites**
- Preparing prerequisite and corequisite software on HP-UX
- Preparing your HP-UX operating system
- Preparing the primary node on HP-UX
- Choosing the type of cluster to create on HP-UX
- Tune your servers

**Configuring Portal Search in a cluster on HP-UX**
To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM WebSphere Application Server node that is not part of the IBM WebSphere Portal cluster.

**Configuring JCR search in a cluster on HP-UX**
To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

**Parent topic:** Setting up a cluster on HP-UX  
**Previous topic:** Tune your servers  
**Next topic:** Setting up multiple clusters on HP-UX
Configuring Portal Search in a cluster on HP-UX

To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM® WebSphere® Application Server node that is not part of the IBM WebSphere Portal cluster.

To install and configure the search service remotely, perform the following tasks:

1. Install and configure the search service to work remotely, that is, on a remote WebSphere Application Server node which is not part of the portal cluster. You can provide the remote search service either as an EJB or as a Web service via SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server node. For details about how to do this, refer to the WebSphere Application Server documentation.

2. Configure the search portlets for remote search service so that they access the remote server accordingly.

Notes:

1. If you have configured a remote search service for a portal cluster, you need to configure the default location for search collections to a directory on the remote server that has write access.

2. The portal site default search collection is created only once at the first time when an administrator selects the search administration portlet Manage Search. If this occurred before you configure the portlet for remote search, then the default portal site search collection is only available on the primary node of the cluster, but not on the remote server. In this case you need to recreate the portal site collection to make it available for search on all nodes of the cluster.

Configuring the default location for search collections
Creating or resetting the portal site collection
Configuring a remote search service
Configuring JCR search in a cluster on HP-UX

To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

Create a shared directory called `jcr/search` on a server in the network and ensure that each node in the cluster and the Deployment Manager has network access to the directory.

**Note:** If you are creating content in a clustered environment using the authoring portlet provided with Web Content Management, additional configuration steps are required to enable content created by these content features to be searchable in a cluster.

Perform the following steps on each server in the cluster to configure Search in a clustered environment:

1. Edit the `icm.properties` file, located in the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory.
2. Change the value of the `jcr.textsearch.indexdirectory` property to the shared directory; for example, `jcr.textsearch.indexdirectory=\\your_server\your_share\jcr\search`. You can specify the shared directory value in one of the following formats: *Table 1. The format for the shared directory.*

<table>
<thead>
<tr>
<th>Format</th>
<th>Shared directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal Naming Convention (UNC) format</td>
<td><code>\\your_server\your_share\jcr\search</code></td>
</tr>
<tr>
<td>Example:</td>
<td><code>\\hostname.example.com\share\jcr\search</code></td>
</tr>
<tr>
<td>Mounted resource format (with forward slashes)</td>
<td><code>/your_share/jcr/search</code> For example: <code>/mnt/jcr/search</code></td>
</tr>
<tr>
<td>Important: This format requires that you mount the shared directory to the local server (for example, through a mapped network drive or a mounted directory). When using the mounted resource format, always use forward slashes instead of back slashes, regardless of the native operating system path format.</td>
<td></td>
</tr>
</tbody>
</table>

3. Required: Perform the following steps to delete the default search collections from the Manage Search portlet:
   A. Log on to WebSphere Portal as an administrator.
   B. Click **Administration > Search Administration > Manage Search**.
   C. Click **Search Collections**.
   D. Click the **Delete Collection** icon for the **Portal Content** search collection.
   E. Click **OK**.
   F. Restart the WebSphere_Portal server.
   G. Go to the Manage Search portlet and confirm that the **Portal Content** search collection was deleted.

**Parent topic:** Configuring search in a cluster on HP-UX
Setting up multiple clusters on HP-UX

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM® WebSphere® Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

Before attempting alternative approaches for building multiple portal-based clusters within a single cell, please contact IBM.

- Prerequisites
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX
  - Tune your servers

1. Installing multiple clusters in a single cell on HP-UX
   Create a new, independent IBM WebSphere Portal cluster in a cell where a WebSphere Portal cluster already exists.

2. Routing requests across clusters on HP-UX
   The HTTP Server plug-in that comes with IBM WebSphere Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

Installing multiple clusters in a single cell on HP-UX

Create a new, independent IBM® WebSphere® Portal cluster in a cell where a WebSphere Portal cluster already exists. In the following steps, **Cluster A** will be used to describe the existing cluster. **Portal B** will be used to describe the new server profile that will be the basis for the new cluster definition, **Cluster B**. Perform the following steps to install multiple clusters in a single cell:

1. Upgrade **Cluster A**, including the Deployment Manager node, to the current, supported hardware and software levels and to the current version of IBM WebSphere Portal.
2. Install and configure **Portal B**; see the "Preparing the primary node" topic for the appropriate operating system for details. **Important:** Maintain the same number of data sources with identical names to the **Cluster A** data sources so that data source bindings in the applications can be resolved on every cluster in which they run. If implementing database sharing across the clusters, the above statement refers to both the shared and non-shared domains; all domains should use the same names.
3. Optional: Using the same database user ID and password for each identically named domain/data source will allow the existing JAAS Authentication Aliases to be functional. If unique database user ID and password are required, additional manual configuration is needed to create new JAAS Authentication Aliases for each data source and map these accordingly. On the primary node of **Cluster A**, run the `./ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=dmgr_password` task from the `wp_profile_root/ConfigEngine` directory to create the new JAAS Authentication Aliases. where `authDomainList` is set to a list of domains which use unique database user ID and passwords and those domain properties are set correctly in the `wkplc_comp.properties` file, including user ID and password.
4. Optional: If necessary, upgrade **Portal B** to the current cumulative fix.
5. Run the `./ConfigEngine.sh mapped-app-list-create -DWasPassword=password` task from the `wp_profile_root/ConfigEngine` directory to build an inventory list of **Portal B** enterprise applications and portlets.
6. Stop the server1 and WebSphere_Portal servers on **Portal B** and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory:
   - Set `WasSoapPort` to the deployment manager's port.
   - Set `WasRemoteHostName` to the full host name of the deployment manager.
7. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   **Important:** Ensure that you set `WasUserid` and `WasPassword` to the Deployment Manager user ID and password.
8. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` of the primary node.
9. Run the `./ConfigEngine.sh map-apps-to-server -DWasPassword=password` task to determine which applications from the inventory list are no longer mapped to **Portal B**. The task uses the application profiles already in the cell to restore the mappings. Wait 30 minutes after running this task to allow all EAR files to expand before proceeding to the next step.
10. Perform the following steps to federate **Portal B** into the deployment manager cell:
   A. Ensure that all database parameters are correctly set, including passwords, in the `wkplc_comp.properties` and `wkplc_dbtype.properties` files.
B. Run the "./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password" task.

C. After running the cluster-node-config-post-federation task, wait at least 30 minutes to allow all EAR files to expand.

D. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the "./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid" task, from the wp_profile_root/ConfigEngine directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.

Important: If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the wp-change-portal-admin-user task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the wp-change-portal-admin-user task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

Note: The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the wp-change-portal-admin-user task. -DnewAdminPw is an optional parameter to update the Administrative password in the wkplc.properties file if required.

E. From the administrative console, click System Administration > Node Agents.

F. Check the box next to the required node agent and then click Restart.

G. Stop and restart the deployment manager.

H. Stop and restart the WebSphere_Portal server on Portal B.

11. Restart the WebSphere_Portal server on Cluster A. Verify that Cluster A is functionally intact by spot checking pages and portlets and then verify that Portal B is functionally intact by spot checking pages and portlets that you deployed into Portal B before it was federated. Any discrepancies or errors should be corrected now before continuing. Note: If Portal B is using a non-default Portal server administrative ID, not wpsadmin, the server will not be functional until the cluster configuration is complete and the Portal administrative ID has been configured to match the Cells security settings.

12. Choose one of the following options to define a cluster using Portal B as the basis:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>

1484
Perform the following steps to define a static cluster using Portal B as the basis:

- Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task.

Configure the cluster to use an external Web server to take advantage of features such as workload management.

Choose one of the following options:

- Configuring a Web server and an application server on separate machines (remote)
- Configuring a Web server and an application server profile on the same machine
- Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard.

Perform the following steps to access the Web Content Management content through an external Web server:

- Log on to the deployment manager administrative console.
- Select Environment > WebSphere Variables. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
- Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
- Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
- Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere_Portal servers.
- Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:
  - Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
  - Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Dynamic cluster

Perform the following steps to define a dynamic cluster using Portal B as the basis:

Log on to the deployment manager administrative console.

Perform the following steps to create a node group:

1. Click **New**. Type the node group **Name**. Type any information about the node group in the **Description** text box.
2. Click **OK**. Click the **Save** link to save your changes to the master configuration.

Perform the following steps to add members to the node group:

1. Click **System administration > Node groups**. Click on the name of the node group that you want to add members to.
2. Click **Node group members** under **Additional Properties**. Click **Add**. Select the primary node and then click **Add**. Click the **Save** link to save your changes to the master configuration.

Perform the following steps to create a dynamic cluster in the node group:

1. Click **Servers > Dynamic clusters**. Click **New**. Select WebSphere Application Server from the **Server Type** pull-down menu and then click **Next**. Type the cluster name in the **Dynamic cluster name** text box and then click **Next**. Type the same value that you provided for the **ClusterName** parameter in the wkplc.properties file of your primary node.
2. Remove all default membership policies and then click **Subexpression builder**. Enter the following information in the Subexpression builder window:
   - **Logical operator** pull-down menu: **and**
   - **Select operand** pull-down menu: **Nodegroup**
   - **Operator** pull-down menu: **Equals (=)**
   - **Value** text box: Type the nodegroup name you created in the previous step.
3. Click **Generate subexpression**. Click **Append**. Click **Preview membership** to verify that all nodes included in the nodegroup display and then click **Next**. Click the **Create the cluster member using an existing server as a template** radio button and then select the WebSphere Portal server for the primary node from the pull-down menu.
4. Click **Next**. Specify the dynamic cluster properties and then click **Next**. Review the summary page to verify your actions and then click **Finish**.

Define or verify the following parameters in the wkplc.properties file, located in the **wp_profile_root**/ConfigEngine/properties directory:

- **ClusterName** to the name of the new dynamic cluster.
- **CellName** is set to the deployment manager cell.
- **NodeName** is set to the local WebSphere Portal node.
- **ServerName** to the server that will be used for the dynamic cluster member on this node.
- **PrimaryNode** is set to true.

Run the **./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password** task from the **wp_profile_root**/ConfigEngine directory to create the dynamic
13. Install any additional nodes to the cell to support additional cluster members for Cluster B identically to the primary node, and then federate as them as secondary nodes and define as cluster members on these nodes. For information about adding additional nodes navigate to Installing WebSphere Portal > Setting up WebSphere Portal > Setting up a clustered production environment. Select Environment > WebSphere Variables. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere Portal servers. If you are using a Web server to connect to the On Demand Router (ODR), configure the web server as a trusted proxy on the ODR. Refer to Configuring a Web server as a trusted proxy server for instructions. Tip: You can also configure the ODR to dynamically update the Web server configuration when changes occur. Refer to Configuring an on demand router to dynamically update the Web server plug-in configuration for instructions. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information: Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup.

14. Restart the server1 and WebSphere_Portal servers on Cluster A and Cluster B.

15. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

Installation of Cluster B is complete. It is now an independent cluster from Cluster A, which means that Cluster B can have its own configuration, set of end-user portlets, and target community. Any applications that are common between Cluster A and Cluster B are most likely infrastructure or related to administration, and special care needs to be taken to preserve their commonality between clusters and correct maintenance levels.

Parent topic: Setting up multiple clusters on HP-UX
Next topic: Routing requests across clusters on HP-UX
Related tasks
Deleting passwords from properties files
Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Routing requests across clusters on HP-UX

The HTTP Server plug-in that comes with IBM® WebSphere® Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

**Prerequisites**

- Installing multiple clusters in a single cell on HP-UX

An important consideration in a multiple cluster environment is ensuring that all subsequent HTTP requests for an end user are routed to the same cluster that processed the first HTTP request. The WebSphere Portal login processing depends upon preserving this cluster affinity during this initial time until the user has successfully logged in and session cookies maintain affinity. In order to guarantee that affinity is preserved during login, set the Navigator Service public.session parameter to a value of true. Refer to "Portal Configuration Services" for information on how to configure this parameter.

**Parent topic:** Setting up multiple clusters on HP-UX

**Previous topic:** Installing multiple clusters in a single cell on HP-UX
Sharing database domains between clusters on HP-UX

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM® WebSphere® Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on HP-UX
  - Preparing your HP-UX operating system
  - Preparing the primary node on HP-UX
  - Choosing the type of cluster to create on HP-UX
  - Tune your servers

**Important:** JCR domains and release domains cannot be shared between different Web Content Management clusters or servers. Each distinct cluster or server in your Web Content Management system must use a separate JCR or release domain. For example:

<table>
<thead>
<tr>
<th>Development Server</th>
<th>Authoring Cluster</th>
<th>Staging Server</th>
<th>Delivery Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>JCR Domain 1</td>
<td>JCR Domain 2</td>
<td>JCR Domain 3</td>
<td>JCR Domain 4</td>
</tr>
<tr>
<td>Release Domain 1</td>
<td>Release Domain 2</td>
<td>Release Domain 3</td>
<td>Release Domain 4</td>
</tr>
</tbody>
</table>

Perform the following steps to share database domains when setting up an environment with multiple clusters:

1. Set up the first cluster (referred to as Cluster A in these instructions).
2. Determine which database domains you want to share with any other clusters in the environment.
3. Install the primary node of the next cluster (Cluster B), and perform the following steps to configure the node to use the shared database domains.
   A. Perform a partial database transfer of the database domains that you are not sharing. For example, if you are sharing only the Customization and Community domains, you would transfer the remaining domains to the database you are using for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.
4. Continue setting up the primary node as described in the cluster instructions.
5. Install the secondary node of Cluster B, and perform the following steps to configure the node to use the shared database domains.
   A. For those database domains that you are not sharing between clusters, reconfigure the domains to connect to the database domains you are using for Cluster B. As in the example for the primary node, if you are sharing only the Customization and Community domains, reconfigure the remaining domains on the secondary node to use the domains of the primary node for Cluster B.
B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.

6. Continue setting up the secondary node as described in the cluster instructions.

Connecting to existing database domains
Setting up a cluster on IBM i5/OS

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

**Prerequisites**

- [Technotes for installation and configuration issues](#)

Perform the following tasks to set up your production environment on i5/OS:

1. **Preparing prerequisite and corequisite software on IBM i5/OS**
   
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your IBM i5/OS**
   
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on IBM i5/OS**
   
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Creating the cluster on i5/OS**
   
   After installing IBM WebSphere Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

5. **Preparing the Web server when portal is installed on IBM i5/OS**
   
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Preparing user registries on IBM i5/OS**
   
   Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

7. **Configuring WebSphere Portal to use a user registry on IBM i5/OS in a clustered environment**
   
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

8. **Preparing additional nodes on IBM i5/OS**
   
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

9. **Optional: Rendering documents on IBM i5/OS**
   
   In order to enable document preview functionality for IBM Lotus Web Content Management and the Common Mail portlet, you must set up an HTML rendering server to work with WebSphere Portal. Because IBM i5/OS does not contain native graphics support, you must install additional fonts to perform the document conversion required by these functions. Document conversion enables WebSphere Portal to convert documents produced by commonly used office programs into Web pages, so that they can be viewed and searched by users online. The additional fonts include an
10. **Tune your servers**

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

11. **Configuring search in a cluster on i5/OS**

IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

12. **Setting up multiple clusters on IBM i5/OS**

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere.Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

13. **Sharing database domains between clusters on IBM i**

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

**Parent topic:** Setting up a cluster
Preparing prerequisite and corequisite software on IBM i5/OS

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. **Preparing the WebSphere Application Server Deployment Manager on i5/OS**
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. **Preparing the Web server when portal is installed on IBM i5/OS**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

Parent topic: Setting up a cluster on IBM i5/OS

Next topic: Preparing your IBM i5/OS
Preparing the WebSphere Application Server Deployment Manager on i5/OS

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command: cd_root/ISERIES/architecture/ifpackage/NAS/install, where cd_root is the root directory of the disc and architecture is the system's processor architecture.

2. Use the manageprofile commands to create a deployment manager profile; see Profile concepts.

3. Run the following command to start the deployment manager: startManager, from the dmgr_profile_root/bin directory.

4. Use the following URL to launch the network deployment administrative console: http://dmgr_hostname:9060/ibm/console, where dmgr_hostname is the fully qualified host name for the WebSphere Application Server Network Deployment.

5. Log into the deployment manager administrative console.

6. Increase the HTTP connection timeouts for the deployment manager.
   A. Click System Administration > Deployment Manager > Web container transport chains.
   B. Increase the timeout values. For the WCInboundAdmin and WCInboundAdminSecure entries listed in the web container transport chains section, complete the following steps to increase the timeout values:
      1. Click HTTP Inbound Channel.
      2. Change the Read timeout value to 180.
      3. Change the Write timeout value to 180.
      4. Save the configuration changes.

7. Change the timeout request period for the Java Management Extensions (JMX) connector.
   A. Click System administration > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties.
   B. Select the requestTimeout property, and increase the value from 600 to 6000.
   C. Save the configuration changes.

8. Update the maximum Java heap size used by the deployment manager:
   B. Update the value in the Maximum Heap Size field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management Product Documentation page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.
   C. Click OK and then save your changes.

9. Click Security > Global security and select Enable Application Security. Then save the configuration changes.  
   **Note:** If security is not enabled on your deployment manager, see Enabling security for information before performing this step.

10. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:
A. Click Users and Groups > Manage Users.
B. Click Create.
C. Type the information for the WebSphere Portal administrative users; for example wpsadmin and wpsbind, and then click Create.
D. Click Users and Groups > Manage Groups.
E. Click Create.
F. Type wpsadmins as the name of the WebSphere Portal administrative group and then click Create.
G. Click the group you just created; for example wpsadmins.
H. Click the Members tab.
I. Click Add Users.
J. Search for the users.
K. Select the users you want to add to the group.
L. Click Add to add the users to the group.
M. Click Close when you are done adding users to the group.
N. Log out of the administrative console.

12. Run the following tasks to stop and restart the deployment manager:
   A. stopManager -username admin_userid -password admin_password, from the dmgr_profile_root\bin directory
   B. startManager, from the dmgr_profile_root\bin directory

Related tasks
Back up the Deployment Manager profile on i5/OS
Restoring the Deployment Manager profile
Preparing the Web server when portal is installed on IBM i5/OS

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on i5/OS
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the **NOTES.INI** file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the **httpd.conf** file on the Web server. Set the `AllowEncodedSlashes` directive to `On`; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server documentation</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>See the appropriate Apache Server documentation</td>
<td><code>AllowEncodedSlashes</code> directives</td>
</tr>
</tbody>
</table>

4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **If using WebDAV**: After successfully installing the Web server plug-in, locate and open your **plugin-cfg.xml** file and set `AcceptAllContent` to `true`.

**Important**: Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your **plugin-cfg.xml** file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.
Preparing your IBM i5/OS

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS

WebSphere Portal can be installed locally or remotely using a Windows workstation.

You need the following information to install remotely:
- A supported version of Microsoft® Windows®
- Workstation CD-ROM drive
- TCP/IP connection to the IBM i5/OS system where you will install WebSphere Portal
- The IBM i5/OS server must be in an unrestricted state
- A valid user ID and password on the IBM i5/OS system
- A user profile with a user type (user class) of *SECOFR (other than QSECOFR) to install and configure WebSphere Portal

You need the following information to install locally:
- IBM i5/OS CD-ROM drive
- The IBM i5/OS server must be in an unrestricted state
- A valid IBM i5/OS user ID and password
- A user profile with a user type (user class) of *SECOFR (other than QSECOFR) to install and configure WebSphere Portal

**Parent topic:** Setting up a cluster on IBM i5/OS

**Previous topic:** Preparing prerequisite and corequisite software on IBM i5/OS

**Next topic:** Preparing the primary node on IBM i5/OS
Preparing the primary node on IBM i5/OS

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS

Perform the following tasks to prepare your primary node:

1. **Installing WebSphere Portal on IBM i5/OS on the primary node**
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. **Configure WebSphere Portal to use a remote database**
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for failover.

3. **Configuring the primary node to communicate with the deployment manager on i5/OS**
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. **Removing search collections on IBM i5/OS**
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Parent topic:** Setting up a cluster on IBM i5/OS  
**Previous topic:** Preparing your IBM i5/OS  
**Next topic:** Creating the cluster on i5/OS
Installing WebSphere Portal on IBM i5/OS on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. Setup a static IP address on the server where you will install WebSphere Portal.
4. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
   - Scripted Administration
   - Administrative Console
   - Ant and Deployment Tools
   - Deploy Tool
   - Ant Utilities

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:
   - **Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.
   - **Restriction:** When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

   Table 1. Installation task options

<td>install.sh -options &quot;path_to_file\response_filename&quot;, where <code>path_to_file</code> is the full path to the response file and <code>response_filename</code> is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. <strong>Important:</strong> Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

6. Verify your installation was successful; access WebSphere Portal using the `http://yourserver:yourport/wps/portal` format. Run the `ConfigEngine.sh list-server-ports -DWwasPassword=password` task from the `wp_profile_root`/ConfigEngine directory to generate the `wp_profile_root`/ConfigEngine/log/wp_PortMatrix.txt file that lists the WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the `ConfigEngine.sh configure-express -DPortalAdminPwd=password -DWwasPassword=password` task from the `wp_profile_root`/ConfigEngine directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

**Restriction:** Run the `configure-express` task before configuring your database, user registry, context root, security, etc. If you ran any tasks other than the install task, do not run this task.

**Note:** See [http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html](http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart.ovw.html) for tutorials on how to use the sample content.

The sample content includes:
- Creates a group called contentAuthors; members of this group are given privileges to create content in the sample
Internet and intranet sites. Navigate to the Administration area and then click Access > Users and Groups.

- Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0".

Navigate to the Administration area and then click Portal Content > Web Content Libraries.

- Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the Environment area.

- Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to Theme Customizer and then select the style.

- Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.

- Creates two virtual portals with context roots of wps/portal/intranet and wps/portal/internet. These are the sample Internet and intranet sites. Go to http://yourserver:yourport/wps/portal/internet and http://yourserver:yourport/wps/portal/intranet to access them.

- Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the Administration area and then click Access > Credential Vault > Manage System Vault Slots.

- Modifies the portlet palette to include some new portlets. Click the Portlets link to see the portlet palette.

Optional: If you ran the configure-express task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as uid=xyzadmin,o=defaultWIMFileBasedRealm. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:

A. Edit the wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following line to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
```

Replace portal_admin_DN with the distinguished name of the portal administrator.

C. Save your changes and close the file.

D. Run the ConfigEngine.sh action-express-memberfixer -DPortalAdminPwd=password -DWasPassword=password task, located in the wp_profile_root/ConfigEngine directory.

If you installed WebSphere Portal on an i5/OS Version 6.1 system, install the MF45016 fix; see Fix Central to access the fix.

Set the following two cache properties under the WP_CacheManagerService resource environment provider in the WebSphere Application Server Administrative Console; see Setting service configuration properties for information:

- cacheglobal.softref=true
- cacheglobal.lifetime=1200

Parent topic: Preparing the primary node on IBM i5/OS

- Advanced installation parameters
Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

**Password considerations when transferring data manually**

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts.

Alternatively, you can specify the password on the command line using the following syntax:

- **Windows**: `ConfigEngine.bat task_name -Dpassword_property_key=password_value`
- **UNIX**: `./ConfigEngine.sh task_name -Dpassword_property_key=password_value`
- **i5/OS**: `ConfigEngine.sh task_name -Dpassword_property_key=password_value`

As with other properties, each password property must have the `-D` prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each `-Dproperty=value` setting.

**Prerequisites**

- Installing WebSphere Portal on IBM i5/OS on the primary node
- [Technote for database connectivity issues](#)

**Parent topic:** Configure WebSphere Portal to use a remote database
Preparing for creation of databases

View the mandatory preparation tasks prior to creating databases that are required by WebSphere Portal. The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Preparing database domain property values prior to creating database names and schemas. Before you manually configure your database schemas, you must first edit your database domain properties files.

1. **Preparing database domain property values prior to creating database names and schemas.** Before you manually configure your database schemas, you must first edit your database domain properties files.

   A. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   B. The WebSphere Portal database can be used to hold information for applications such as Personalization (Feedback) and LikeMinds. To prepare the database to hold such application information, you should use similar naming conventions for property values such as `release.DbName`. Here are some examples:

   - `release.DbName=hostname/ WP61REL`
   - `community.DbName=hostname/ WP61COM`
   - `customization.DbName=hostname/ WP61CUS`
   - `jcr.DbName=hostname/ WP61JCR`
   - `feedback.DbName=hostname/ WP61FBK`
   - `likeminds.DbName=hostname/ WP61LKM`

   When you create a schema, you must use the following schema naming conventions on the i5/OS system: **Note:** The default schema names may be used with the product.

   - Length cannot exceed 10 characters
   - All alphanumerical characters are allowed ("A" through "Z" and "1" through "0")
   - The following characters are invalid:
     - spaces
     - null values
     - asterisk (*)
     - quotation marks ("")
     - colon (:)
     - greater than symbol (>)
     - less than symbol (<)
     - vertical bar (!)
- plus sign (+)
- semicolon (;)
- single quotation mark (’)
- question mark (?)

Notes:
- Make sure you know what valid schema names are and do not use a schema name which already exists on the local or remote system. Follow the documentation of the target database management system in order to define a valid schema name as restrictions apply. Note that the Create WebSphere Portal wizard will automatically check schema names for you.
- For more information on database and schema naming conventions, refer to DB2 Universal Database for System i5 topic in the System i5 information center.

- Do not change any settings other than those that are specified in these substeps.
- If you are using a remote database, be sure to enter the values for the remote server.
- Use / instead of \ for i5/OS.
- Some values, shown here in italics, might need to be modified to your specific environment.
- Password considerations: For security reasons, you should not store passwords in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files. It is recommended that you edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. Then, after the task has run, you should delete all passwords from each file.
- There might be additional database properties other than those listed here. Only change the properties within this table; skip all other properties.
- Depending on which database domain has to be configured, the variable dbdomain may need to be replaced by:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds

C. Use a text editor to open the properties files and enter the values that are appropriate for your environment. You can also modify each properties file locally on your System i5 system by typing the following on an OS/400 command line in a 5250 session: EDTF 'wp_profile_root/ConfigEngine/properties/property_filename.properties'

Note: You must have a user profile on the System i5 server and must have at least *USE special authority to edit the properties file.

Tip: The steps for transferring data to another supported database section provide instructions for manually transferring data. Instead of performing the following steps, you can use the configuration wizard, which is a graphical user interface, to transfer data to another supported database.

The following properties must be changed before creating a database name and schema on a local or remote System i5 server.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomain.DbType, type db2_iseries.
   B. For dbdomain.DbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomain.DbUrl property.
   C. For dbdomain.DbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have
schema name restrictions that you need to understand.

D. For \texttt{dbdomain.DataSourceName}, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
- releaseDS
- communityDS
- customizationDS
- jcrDS
- lmdbDS
- feedback

E. For \texttt{dbdomain.DbUrl}, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. \textbf{Note:} The database element of this value should match the value of DbName.

F. For \texttt{dbdomain.DbUser}, type the user ID for the database administrator.

G. For \texttt{dbdomain.DbPassword}, type the password for the database administrator.

H. For \texttt{dbdomain.DBA.DbUser}, type the database administrator user ID for privileged access operations during creation of the database.

I. For \texttt{dbdomain.DBA.DbPassword}, type the database administrator password for privileged access operations during creation of the database.

3. Save and close the file.

4. Update the following properties in the file \texttt{wkplcDbType.properties}.
   A. For \texttt{db2_iseries.DbDriver}, type the name of the class that \texttt{SqlProcessor} uses to import SQL files.
   B. For \texttt{db2_iseries.DbLibrary}, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
   C. For \texttt{db2_iseries.JdbcProviderName}, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.
   D. For \texttt{db2_iseries.DbDriverType}, type the number representing the driver type for the database.

5. Save and close the file.

6. Update the following property in the file \texttt{wkplc.properties}.
   A. For \texttt{WasPassword}, type the password for the WebSphere Application Server security authentication used in your environment.

7. Save and close the file.

\textbf{Parent topic:} Preparing DB2 for i5/OS  
\textbf{Next topic:} Create user profiles
Create user profiles

View information on setting up user profiles for DB2 for i5/OS to work with WebSphere Portal.

Before you begin:
- The user profile for the database owner should be different from the administrator user profile used to perform the installation. The administrator user profile may have more authority than is required and usually belongs to an individual, whereas the database user profile may have minimal authority and can be shared.
- Create a database user profile that does not require a password change over a period of time. If the password for the database user profile changes, WebSphere Portal must be re-configured to use the new password.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

- Prerequisites
  - Preparing for creation of databases

To create user profiles, follow the instructions that are provided with the DB2 for i5/OS documentation.

Parent topic: Preparing DB2 for i5/OS
Previous topic: Preparing for creation of databases
Next topic: Creating remote databases
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before you begin:
- The user ID and password used must have the authority to create database libraries on the remote System i5 machine.
- For every property instance of a database that uses "LOCAL/schema, replace it with HostName/schema. For example, the default database and database library name for WebSphere Portal release domain is release.DbName=wpsdb. If you wanted to create this database library on a remote database, change the default value to release.DbName=hostname/wpsdb.

- **Prerequisites**
  - Preparing for creation of databases
  - Create user profiles

To create all the domain database libraries, perform the following steps:

1. Start a 5250 session on the remote database machine.
2. Type the i5/OS command **WRKRDBDIRE** to display the Relational Database Directory Entry for Remote Location "LOCAL" and make a note of the value displayed.
3. Sign off from the 5250 session.
4. Start a 5250 session on the local machine where WebSphere Portal is installed.
5. Create a Relational Database Directory Entry on the local system for the remote system using i5/OS command **WRKRDBDIRE**.
6. Add an entry with the following values:
   - **Relational database**
     - The remote relational database. Use the value noted from the prior step.
   - **Relational database alias**
     - The hostname. Use the short TCP/IP hostname of the remote system
   - **Remote location**
     - The domain qualified hostname. Use the full TCP/IP hostname of the remote system
   - **Type**
     - IP
   - **Port number or service name**
     - DRDA
   - **Remote authentication method**
     - Preferred method: ENCRYPTED
     - Allow lower authentication: ALWLOWER
7. Create the required DB2 packages on the remote database machine by running the following command from the local machine:
   ```
   JAVA CLASS(com.ibm.db2.jdbc.app.DB2PackageCreator) PARM('rdb_alias' 'userid' 'password')
   PROP((jdbc.drivers 'com.ibm.as400.access.AS400JDBCDriver'))
   ```
   where **rdb_alias** matches the name of the Relational Database Entry you created in step 2, where **userid** is the database administrator user ID on the remote machine, and where **password** is the database administrator password on the remote machine. The output should be:
   
   Java program completed
8. Press F3 to exit Java Shell Display.
9. Sign off from the 5250 session.
10. Start a 5250 session on the remote database machine.
11. Verify the required DB2 packages were created by running the command `WRKOBJ OBJ(QGPL/QSQCL*) OBJTYPE(*SQLPKG)`

```
<table>
<thead>
<tr>
<th>Object</th>
<th>Type</th>
<th>Library</th>
<th>Attribute</th>
<th>Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>QSQCLIPKGA</td>
<td>*SQLPKG</td>
<td>QGPL</td>
<td>PACKAGE</td>
<td></td>
</tr>
<tr>
<td>QSQCLIPKGC</td>
<td>*SQLPKG</td>
<td>QGPL</td>
<td>PACKAGE</td>
<td></td>
</tr>
<tr>
<td>QSQCLIPKGL</td>
<td>*SQLPKG</td>
<td>QGPL</td>
<td>PACKAGE</td>
<td></td>
</tr>
<tr>
<td>QSQCLIPKGN</td>
<td>*SQLPKG</td>
<td>QGPL</td>
<td>PACKAGE</td>
<td></td>
</tr>
<tr>
<td>QSQCLIPKGS</td>
<td>*SQLPKG</td>
<td>QGPL</td>
<td>PACKAGE</td>
<td></td>
</tr>
</tbody>
</table>
```

12. Start a 5250 session on the local machine where WebSphere Portal is installed.
13. On the command line, enter the following to change directories: `cd wp_profile_root/ConfigEngine`.
14. Press Enter.
15. Change the property values in the configuration properties files before entering the following on the command line:

```
ConfigEngine.sh create-database
```
16. Press Enter.

**Parent topic:** Preparing DB2 for i5/OS  
**Previous topic:** Create user profiles  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Preparing for creation of databases
  - Create user profiles
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:

  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - dbdomain.DbType
- **dbdomain**.DbName
- **dbdomain**.DbUrl
- **dbdomain**.DbSchema

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If **DbUser**, **DbUrl**, and **DbPassword** are not the same across domains, the value for **DataSourceName** must differ from the **DataSourceName** of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In **wkplc_comp.properties**, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   A. For **dbdomain**.DbType, type `db2_iseries`.
   B. For **dbdomain**.DbName, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the **dbdomain**.DbUrl property.
   C. For **dbdomain**.DbSchema, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For **dbdomain**.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For **dbdomain**.DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of DbName.
   F. For **dbdomain**.DbUser, type the user ID for the database administrator.
   G. For **dbdomain**.DbPassword, type the password for the database administrator.

3. **(Optional)** When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in **wkplc_comp.properties**. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.
   A. For **source.domain**.DbType, type of the database you are currently configured to use. The value for **source.domain**.DbType is Derby by default.
   B. For **source.domain**.DbName, type the name of the database domain you are currently using.
   C. For **source.domain**.DbSchema, type current schema identifier for objects within the database for this domain.
   D. For **source.domain**.DataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For \textit{source.domain}.DbUrl, type the url currently used to access your database.

F. For \textit{source.domain}.DbUser, type the name of the user accessing this database.

G. For \textit{source.domain}.DbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file \texttt{wkplc_dbtype.properties}.
   
   A. For db2\_iseries.DbDriver, type the name of the class that \texttt{SqlProcessor} uses to import SQL files.

   B. For db2\_iseries.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For db2\_iseries.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file \texttt{wkplc.properties}.
   
   A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

\textbf{Parent topic:} Preparing DB2 for i5/OS  
\textbf{Previous topic:} Creating remote databases  
\textbf{Next topic:} Transferring DB2 for i5/OS manually
Transferring DB2 for i5/OS manually

View the steps to manually transfer data to the IBM® DB2 Universal Database™ for iSeries® database you have set up. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.

- **Prerequisites**
  - Preparing for creation of databases
  - Create user profiles
  - Creating remote databases
  - Modifying database properties

**Steps for transferring data to another supported database**

1. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>stopServer server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td>stopServer WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

2. Validate configuration properties using the following commands:

   ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password

   ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password

3. Transfer the database: **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   **A.** Enter the following command:

   ```sh
   ConfigEngine.sh database-transfer -DWasPassword=password
   ```

   **Note:**

   - To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

   ```sh
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```

   - Use SBMJOB to submit the Qshell script as a batch job to run in *BASE pool when *INTERACT pool does not have 1GB or more of allocated memory. For example:

   ```sh
   SBMJOB CMD(STRQSH CMD(ConfigEngine.sh database-transfer -DWasPassword=password))
   ```

   **B.** After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files and then repeat this step.
4. Enter the following command to start the WebSphere Portal server:

```
startServer WebSphere_Portal
```

If you have performed database transfer in a clustered environment, you must explicitly copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node on which the database-transfer task was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values specified in the `icm.properties` file.

1. Stop the portal server on the secondary node.
2. Copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node and replace the `icm.properties` file on the secondary node with the new file from the primary node.
3. Start the portal server on the secondary node.

**Parent topic:** Preparing DB2 for i5/OS

**Previous topic:** Modifying database properties

**Next topic:** Verifying database connections
Verifying database connections

After WebSphere Portal is configured to work with your database, test the database connection to ensure that it operates correctly.

- **Prerequisites**
  - Preparing for creation of databases
  - Create user profiles
  - Creating remote databases
  - Modifying database properties
  - Transferring DB2 for i5/OS manually

You can verify the connection from a browser or from a command line. To verify that WebSphere Portal is running from a browser, open the portal in a Web browser: http://hostname.yourco.com:port_number/wps/portal, where hostname.yourco.com is the fully qualified host name of the machine where WebSphere Portal is running and port_number is the transport port that is created by IBM® WebSphere® Application Server.

There may be an error if any of the following conditions appear.

- When trying to access the portal you get a 503 error.
- If you had any locale problems with your database, you could see invalid characters, such as ????, after logging in. This may happen if the character set of the database is not UTF-8 compliant.
- If something went wrong with the data that was transferred, you may not be able to login. WebSphere Portal will indicate you entered an invalid user ID and password even though you know it is valid.

Verify the connection from a command line by completing the following steps:

1. Start a 5250 session on the local machine where WebSphere Portal is installed.
2. For WebSphere Portal on WebSphere Application Server (UserData path), enter the following on the command line: `cd wp_profile_root/ConfigEngine`
3. Enter the following command: `ConfigEngine.sh validate-database-connection -DTransferDomainList=release,community,customization,jcr,feedback,likeminds -DWasPassword=password`

For security reasons, you should not leave passwords in the wkplc_comp.properties file. Edit the file prior to running a configuration task and insert the passwords that are needed for that task. After the task has run, delete all passwords from the file.

Alternatively, you can specify the password on the command line rather than update the wkplc_comp.properties file. For example: `ConfigEngine.sh -DPortalAdminPwd=password -DWasPassword=password validate-wps-admin-login`

When installing WebSphere Portal, the passwords in the wkplc_comp.properties file are automatically removed after configuration.

**Parent topic:** Preparing DB2 for i5/OS

**Previous topic:** Transferring DB2 for i5/OS manually
Configuring the primary node to communicate with the deployment manager on i5/OS

After installing IBM® WebSphere® Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

- Prerequisites
  - Installing WebSphere Portal on IBM i5/OS on the primary node
  - Configure WebSphere Portal to use a remote database

Perform the following step to configure WebSphere Portal to communicate with the deployment manager:

Perform the following steps to collect files from the primary node and copy them to the deployment manager:

1. Run the ConfigEngine.sh collect-files-for-dmgr -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory of the primary node, to create an archive or compressed file containing all the files which need to be copied to the Deployment Manager. **Note:** The archive or compressed file will be placed in the wp_profile_root/filesForDmgr directory and the file will be called filesForDmgr.zip.

2. Stop the deployment manager.

3. Expand the filesForDmgr.zip file into the installation root directory of the Deployment Manager; for example this may be a subdirectory under the AppServer directory and it will contain the bin and profileTemplates directories. **Note:** If the Deployment Manager profile was not created in the default AppServer/profiles/Dmgr01 directory, then the metadata_wkplc.xml file, located in the AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml directory in the zip file, must be placed into the correct Deployment Manager profile directory.

4. If the Deployment Manager profile is running on the same application server where WebSphere Portal is installed, remove the com.ibm.ws.portletcontainer.deploytask_6.1.5.jar file from the AppServer/plugins directory.

5. Start the deployment manager.

**Parent topic:** Preparing the primary node on IBM i5/OS

**Previous topic:** Configure WebSphere Portal to use a remote database

**Next topic:** Removing search collections on IBM i5/OS

**Related tasks**

Configuring Portal Search in a cluster on i5/OS
Removing search collections on IBM i5/OS

If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

- Prerequisites
  - Installing WebSphere Portal on IBM i5/OS on the primary node
  - Configure WebSphere Portal to use a remote database
  - Configuring the primary node to communicate with the deployment manager on i5/OS

Perform the following step to remove the search collection:

Perform the following steps to delete all existing search collections from the primary node:

1. Log on to WebSphere Portal.
2. Navigate to Administration > Search Administration > Manage Search and then click Search Collections.
3. Click the Delete Collection icon for each search collection and then click OK until they are all deleted.
4. Restart the WebSphere_Portal server and then navigate back to the Search Collections page to verify that all search collections have been deleted.

Parent topic: Preparing the primary node on IBM i5/OS

Previous topic: Configuring the primary node to communicate with the deployment manager on i5/OS
Creating the cluster on i5/OS

After installing IBM® WebSphere® Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

**Prerequisites**

- Preparing prerequisite and corequisite software on IBM i5/OS
- Preparing your IBM i5/OS
- Preparing the primary node on IBM i5/OS

Perform the following steps to create the cluster:

1. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the `wp_profile_root/ConfigEngine/properties` directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading. **Important:** Ensure that you set `WasUserId` and `WasPassword` to the Deployment Manager user ID and password.

2. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory:
   - **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
     - A. Set `WasSoapPort` to the port used to connect remotely to the deployment manager.
     - B. Set `WasRemoteHostName` to the full host name of the server used to remotely connect to the deployment manager.
     - C. Verify that `WasPassword` is set to your deployment manager password.
     - D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
     - E. Verify that `ClusterName` is set.
     - F. Verify that `PrimaryNode` is set to `true`.

3. Make a backup copy of the `wp_profile_root/config/cells/cell_name/wim/config/wimconfig.xml` and `wp_profile_root/config/cells/cell_name/wim/model/wimxmlextension.xml`, if available, files.

4. Run the `ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task`, from the `wp_profile_root/ConfigEngine` directory of the primary node. **Note:** If you want to specify custom ports for the nodeagent, add the `-DPortPropsFile=full to portfile` parameter to the `cluster-node-config-pre-federation` task. You can use the ports files that are found on the Setup CD for WebSphere_Portal and server1 as a guide.

   **Note:** You may receive a message about accepting an SSL signer certificate. Failure to accept the SSL signer certificate will cause the script to fail. Alternatively, the `com.ibm.ssl.enableSignerExchangePrompt` flag can be enabled in the `ssl.client.props` file for "DefaultSSLSettings" in order to allow acceptance of the signer during the connection attempt.

   **Warning:** If the `cluster-node-config-pre-federation` fails for any reason, you must perform the following steps before rerunning the task:
   - A. Remove the node if the `AddNode` task succeeded.
   - B. Log on to the deployment manager and perform the following steps if the items exist:
     1. Remove all enterprise applications.
     2. Remove the WebSphere_Portal server definition.
3. Remove the WebSphere Portal JDBC Provider.

**Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following technote: Migrating with Lookaside Data.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.

**Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `ConfigEngine.sh wp-node-prep-vmm-db-secured-environment` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. `Note: VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

- **DB2 for i5/OS Type 2 driver:** `/QIBM/ProdData/Java400/ext/db2_classes.jar`
- **DB2 for i5/OS Type 4 driver:** `/QIBM/ProdData/HTTP/Public/jt400/lib/jt400.jar`

6. Run the `ConfigEngine.sh cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `ConfigEngine.sh wp-change-portal-admin-user` task from the `wp_profile_root` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user` task. If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Run the `ConfigEngine.sh cluster-node-config-cluster-setup` task.
9. Configure the cluster to use an external Web server to take advantage of features such as workload management.
   Choose one of the following options:
   - Recommended remote distributed installation
   - Local distributed installation
   - Setting up multiple clusters on IBM i5/OS

10. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Resynchronize.
   G. Log off of the deployment manager administrative console.

11. Run the following tasks to propagate your changes: **Note:** WebSphere_Portal_nodename is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the serverstatus -all task to get a list of the server names and their status.
   A. stopManager -username admin_userid -password admin_password, from the dmgr_profile_root/bin directory
   B. stopNode -username admin_userid -password admin_password from the wp_profile_root/bin directory
   C. stopServer WebSphere_Portal -username admin_userid -password admin_password
   D. startManager, from the dmgr_profile_root/bin directory
   E. startNode, from the wp_profile_root/bin directory
   F. startServer.sh WebSphere_Portal_nodename

12. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

<table>
<thead>
<tr>
<th>Option</th>

<td>Adding a BPI-enabled portal server to a managed cell in a single-cell setup</td>
</tr>
</tbody>
</table>

**Parent topic:** Setting up a cluster on IBM i5/OS

**Previous topic:** Preparing the primary node on IBM i5/OS

**Next topic:** Preparing the Web server when portal is installed on IBM i5/OS

**Related tasks**
- Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Preparing the Web server when portal is installed on IBM i5/OS

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

**Prerequisites**

- Preparing the WebSphere Application Server Deployment Manager on i5/OS
- Preparing prerequisite and corequisite software on IBM i5/OS
- Preparing your IBM i5/OS
- Preparing the primary node on IBM i5/OS

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `On`; the directive should be added at the root level as a global directive.
4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information.

   **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

   **Important:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.

**Parent topic:** Preparing prerequisite and corequisite software on IBM i5/OS

**Previous topic:** Preparing the WebSphere Application Server Deployment Manager on i5/OS

**Parent topic:** Setting up a cluster on IBM i5/OS

**Previous topic:** Creating the cluster on i5/OS

**Next topic:** Preparing user registries on IBM i5/OS
Preparing user registries on IBM i5/OS

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS

Choose the appropriate LDAP server to install and setup:

- **Preparing a Tivoli Directory Server for IBM i5/OS**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

Parent topic: Setting up a cluster on IBM i5/OS
Previous topic: Preparing the Web server when portal is installed on IBM i5/OS
Next topic: Configuring WebSphere Portal to use a user registry on IBM i5/OS in a clustered environment
Preparing a Tivoli Directory Server for IBM i5/OS

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

1. Customize the LDAP directory servers settings using the Directory Services Configuration Wizard. You must have *ALLOBJ and *IOSYSCFG special authority to use the wizard. Go to IBM System i and IBM i Information Center, select the appropriate Information Center version and navigate to e-business and Web serving > Security and IBM Tivoli Directory Server for i5/OS (LDAP) > IBM Tivoli Directory Server for i5/OS (LDAP) for information. **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Go to IBM System i and IBM i Information Center, select the appropriate Information Center version and navigate to Networking > TCP/IP applications, protocols, and services > IBM Directory Server for iSeries (LDAP) > Administering Directory Server > General administration tasks > Adding and Removing Directory Server suffixes for information.
      2. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on IBM i5/OS
Configuring WebSphere Portal to use a user registry on IBM i5/OS in a clustered environment

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- Prerequisites
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS

Perform the following tasks to configure WebSphere Portal to use a user registry:

1. Choosing your user registry model on IBM i5/OS in a clustered environment

Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Parent topic: Setting up a cluster on IBM i5/OS
Previous topic: Preparing user registries on IBM i5/OS
Next topic: Preparing additional nodes on IBM i5/OS
Choosing your user registry model on IBM i5/OS in a clustered environment

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on IBM i5/OS in a clustered environment**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

- **Adapting the attribute configuration**
  After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

**Parent topic:** Configuring WebSphere Portal to use a user registry on IBM i5/OS in a clustered environment
Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on IBM i5/OS in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on IBM i5/OS in a clustered environment
Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the `wp-modify-ldap-security` task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the `standalone.ldap.realm` parameter or you can set `ignoreDuplicateIDs=true` in the `wkplc.properties` file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory. 
   - Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Stand-alone LDAP configuration heading:
     - `standalone.ldap.id`
     - `standalone.ldap.host`
     - `standalone.ldap.port`
     - `standalone.ldap.bindDN`
     - `standalone.ldap.bindPassword`
     - `standalone.ldap.ldapServerType`
     - `standalone.ldap.userIdMap`
     - `standalone.ldap.groupIdMap`
     - `standalone.ldap.groupMemberIdMap`
     - `standalone.ldap.userFilter`
     - `standalone.ldap.groupFilter`
     - `standalone.ldap.serverId`
     - `standalone.ldap.serverPassword`
     - `standalone.ldap.realm`
     - `standalone.ldap.primaryAdminId`
     - `standalone.ldap.primaryAdminPassword`
     - `standalone.ldap.primaryPortalAdminId`
     - `standalone.ldap.primaryPortalAdminPassword`
     - `standalone.ldap.primaryPortalAdminGroup`
     - `standalone.ldap.baseDN`

   - `Note`: Use the `wp_security_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_security_xxx.properties` helper file.

2. Use the `wp_security_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/properties` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_security_xxx.properties` helper file.
3. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.et.group.objectClasses
   - standalone.ldap.et.group.objectClassesForCreate
   - standalone.ldap.et.group.searchBases
   - standalone.ldap.et.personaccount.objectClasses
   - standalone.ldap.et.personaccount.objectClassesForCreate
   - standalone.ldap.et.personaccount.searchBases

4. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attributes heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.gm.groupMemberName
   - standalone.ldap.gm.objectClass
   - standalone.ldap.gm.scope
   - standalone.ldap.gm dummyMember

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the wkplc.properties file under the Default parent, RDN attribute heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.ldap.personAccountParent
   - standalone.ldap.groupParent
   - standalone.ldap.personAccountRdnProperties
   - standalone.ldap.groupRdnProperties

6. Save your changes to the wkplc.properties file.

7. Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. Note: See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.
   - WcmContentAuthorsGroupId
   - WcmContentAuthorsGroupCN

8. Run the ConfigEngine.sh validate-standalone-ldap -DWasPassword= password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry. Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

9. Run the ConfigEngine.sh wp-modify-ldap-security -DWasPassword= password task, from the wp_profile_root /ConfigEngine directory, to set the standalone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Run the ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword= password task, from the wp_profile_root /ConfigEngine directory, to check that all defined attributes are available in the configured LDAP user registry. Important: When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the configure-express task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. *Value for realm_name when running the Member Fixer task to update the member names used by Web Content Management*

<table>
<thead>

<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone ldap realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment

**Related tasks**

- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring a stand-alone LDAP user registry over SSL on IBM i5/OS in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL: Note: Use the `wp_security_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_security_xxx.properties` helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:

        1. Log in to the WebSphere Application Server Administrative Console.

        2. Navigate to Security > SSL certificate and key management > SSL configurations.

        3. Click the appropriate SSL configuration from the list. For example,

           - Stand-alone environments: `NodeDefaultSSLSettings`
           - Clustered environments: `CellDefaultSSLSettings`

        **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

        4. Click Key stores and certificates.

        5. Click the appropriate trust store from the list; for example, `NodeDefaultTrustStore`.

        6. Click Signer certificates, click Add, and then enter the following information:

           - Type the **Alias** the key store uses for the signer certificate.
           - Type the **File name** where the signer certificate is located.

        7. Click OK and then click Save to save the changes to the master configuration.

   B. Retrieve the certificate from the port:

       1. Log in to the WebSphere Application Server Administrative Console.

       2. Navigate to Security > SSL certificate and key management > SSL configurations.

       3. Click the appropriate SSL configuration from the list. For example,

           - Stand-alone environments: `NodeDefaultSSLSettings`
Clustered environments: **CellDefaultSSLSettings**

Clustered environments: Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

- **Client trust storeNote**: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

A. See **Secure installation for client signer retrieval**.

B. Run the **retrieveSigners** task from the `wp_profile_root\bin` directory; see **retrieveSigners command** for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. **Note**: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

1. Use a text editor to open the `ssl.client.props` file, located in the `wp_profile_root\properties` directory.

2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter

   ```
   com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12
   ```

   to use the default trust store.

3. Save your changes.

2. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

3. **Required**: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Standalone LDAP configuration heading: **Note**: See the properties file for specific information about the required parameters and for advanced parameters.

   - `standalone.idap.id`
   - `standalone.idap.host`
   - `standalone.idap.port`
   - `standalone.idap.blndDN`
   - `standalone.idap.bindPassword`
   - `standalone.idap.idapServerType`
   - `standalone.idap.userldMap`
   - `standalone.idap.groupIdMap`
   - `standalone.idap.groupMemberIdMap`
   - `standalone.idap.userFilter`
   - `standalone.idap.groupFilter`
   - `standalone.idap.serverId`
   - `standalone.idap.serverPassword`
   - `standalone.idap.realm`
   - `standalone.idap.primaryAdminId`
   - `standalone.idap.primaryAdminPassword`
   - `standalone.idap.primaryPortalAdminId`
4. Required: Enter a value for the following required entity types parameters in the \texttt{wkplc.properties} file under the LDAP entity types heading:\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{standalone.ldap.et.group.objectClasses}
- \texttt{standalone.ldap.et.group.objectClassesForCreate}
- \texttt{standalone.ldap.et.group.searchBases}
- \texttt{standalone.ldap.et.personaccount.objectClasses}
- \texttt{standalone.ldap.et.personaccount.objectClassesForCreate}
- \texttt{standalone.ldap.et.personaccount.searchBases}

5. Required: Enter a value for the following required group member parameters in the \texttt{wkplc.properties} file under the Group member attributes heading:\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{standalone.ldap.gm.groupMemberName}
- \texttt{standalone.ldap.gm.objectClass}
- \texttt{standalone.ldap.gm.scope}
- \texttt{standalone.ldap.gm.dummyMember}

6. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the \texttt{wkplc.properties} file under the Default parent, RDN attribute heading:\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

- \texttt{standalone.ldap.personAccountParent}
- \texttt{standalone.ldap.groupParent}
- \texttt{standalone.ldap.personAccountRdnProperties}
- \texttt{standalone.ldap.groupRdnProperties}

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL):\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

Required parameters:

- \texttt{standalone.ldap.sslEnabled}
- \texttt{standalone.ldap.sslConfiguration}

Optional parameters:

- \texttt{standalone.ldap.certificateMapMode}
- \texttt{standalone.ldap.certificateFilter}

8. Save your changes to the \texttt{wkplc.properties} file.

9. Run the \texttt{ConfigEngine.sh \ validate-standalone-ldap -DWasPassword=\textit{password}} task to validate your LDAP server settings.\textbf{Attention:} If you have not deleted the default file repository, \textit{WasPassword} is the value entered during installation and not a value found in your LDAP user registry. 

\textbf{Note:} During the validation task, you may receive the following prompt: Add signer to the trust store now? Press \texttt{y} then \texttt{Enter}.

10. Run the \texttt{ConfigEngine.sh \ wp-modify-ldap-security -DWasPassword=\textit{password}} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to set the standalone LDAP user registry.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: \textit{Starting and stopping servers, deployment managers, and node agents}.

12. Run the \texttt{ConfigEngine.sh \ wp-validate-standalone-ldap-attribute-config -DWasPassword=\textit{password}} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on IBM i5/OS in a clustered environment

**Related tasks**
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring the default federated repository on IBM i5/OS in a clustered environment

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on IBM i5/OS in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on IBM i5/OS in a clustered environment**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on IBM i5/OS in a clustered environment**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

**Parent topic:** Choosing your user registry model on IBM i5/OS in a clustered environment
Configuring a federated LDAP user registry on IBM i5/OS in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- Adding an LDAP user registry on IBM i5/OS in a clustered environment
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName,o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

- Adding an LDAP user registry over SSL on IBM i5/OS in a clustered environment
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

**Parent topic:** Configuring the default federated repository on IBM i5/OS in a clustered environment
Adding an LDAP user registry on IBM i5/OS in a clustered environment

Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM® Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is \texttt{cn=groupName} and the hierarchical format is \texttt{cn=groupName,o=\textit{root}}. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as \texttt{wpsadmin}, this ID cannot exist in the LDAP you are adding.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

\textbf{Tip:} Perform these steps on the primary node only.

\textbf{Note:} Use the \texttt{wp_add_federated\_xxx.properties} helper file, located in the \texttt{wp\_profile\_root/ConfigEngine/config/helpers} directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the \texttt{wkplc.properties} file, you will use your \texttt{wp\_add\_federated\_xxx.properties} helper file.

1. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp\_profile\_root/ConfigEngine/properties} directory.

2. Required: Enter a value for the following required parameters in the \texttt{wkplc.properties} file under the VMM Federated LDAP Properties heading: \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

   - \texttt{federated.ldap.id}
   - \texttt{federated.ldap.host}
   - \texttt{federated.ldap.port}
   - \texttt{federated.ldap.bindDN}
   - \texttt{federated.ldap.bindPassword}
   - \texttt{federated.ldap.ldapServerType}
   - \texttt{federated.ldap.baseDN}

3. Required: Enter a value for the following required entity types parameters in the \texttt{wkplc.properties} file under the LDAP entity types heading: \textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.

   - \texttt{federated.ldap.et.group.objectClasses}
   - \texttt{federated.ldap.et.group.objectClassesForCreate}
   - \texttt{federated.ldap.et.group.searchBases}
   - \texttt{federated.ldap.et.personaccount.objectClasses}
4. Required: Enter a value for the following required group member parameters in the \texttt{wkplc.properties} file under the Group member attribute heading:\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.
- \texttt{federated.ldap.et.personaccount.objectClassesForCreate}
- \texttt{federated.ldap.et.personaccount.searchBases}
- \texttt{federated.ldap.et.personaccount.objectClassesForCreate}
- \texttt{federated.ldap.et.personaccount.objectClassesForCreate}
- \texttt{federated.ldap.et.personaccount.searchBases}

5. Save your changes to the \texttt{wkplc.properties} file.

6. Optional: Enter the following Web content authors parameters in the \texttt{wkplc_comp.properties} file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product.\textbf{Note:} See the \texttt{wkplc_comp.properties} file for specific information about the required parameters and for advanced parameters.
- \texttt{WcmContentAuthorsGroupId}
- \texttt{WcmContentAuthorsGroupCN}

7. Run the \texttt{ConfigEngine.sh validate-federated-ldap -DWasPassword=password} task to validate your LDAP server settings.\textbf{Attention:} If you have not deleted the default file repository, \texttt{WasPassword} is the value entered during installation and not a value found in your LDAP user registry.

\textbf{Note:} During the validation task, you may receive the following prompt: \texttt{Add signer to the trust store now?}. Press \texttt{y} then \texttt{Enter}.

8. Run the \texttt{ConfigEngine.sh wp-create-ldap -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to add an LDAP user registry to the default federated repository.\textbf{Note:} Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: \textit{Starting and stopping servers, deployment managers, and node agents}.

10. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

A. Use a text editor to open the \texttt{wkplc.properties} file, located in the \texttt{wp_profile_root/ConfigEngine/properties} directory.

B. Enter a value for the following required parameters in the \texttt{wkplc.properties} file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:

\textbf{Note:} See the properties file for specific information about the required parameters and for advanced parameters.
- \texttt{id}
- \texttt{baseDN}
- \texttt{nameInRepository}

C. Save your changes to the \texttt{wkplc.properties} file.

D. Run the \texttt{ConfigEngine.sh wp-create-base-entry -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

11. Optional: Run the \texttt{ConfigEngine.sh wp-query-repository -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to list the names and types of configured repositories.

12. Run the \texttt{ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password} task, from the \texttt{wp_profile_root/ConfigEngine} directory, to check that all defined attributes are available in the configured LDAP.
user registry. **Important:** When you finish configuring your LDAP user registry, see “Adapting the attribute configuration” for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

13. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

   A. Edit the `wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

   B. Add the following lines to the file:

   ```
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
   cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
   ```
Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management.

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

16. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

17. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

**Important:**
- Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
- Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root/ConfigEngine` directory: `ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.

B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine` directory: `ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `Dskip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
18. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it.

   The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

   If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

Adding an LDAP user registry over SSL on IBM i5/OS in a clustered environment

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the wp_add_federated_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_add_federated_xxx.properties helper file.

To specify the LDAP server’s SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:

- **Server trust store**
  A. Add the certificate to the trust store:
    1. Log in to the WebSphere Application Server Administrative Console.
    2. Navigate to Security > SSL certificate and key management > SSL configurations.
    3. Click the appropriate SSL configuration from the list. For example,
      - **Stand-alone environments:** NodeDefaultSSLSettings
      - **Clustered environments:** CellDefaultSSLSettings
    4. **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
    5. Click Key stores and certificates.
    6. Click Signer certificates, click Add, and then enter the following information:
      - Type the Alias the key store uses for the signer certificate.
      - Type the File name where the signer certificate is located.
    7. Click OK and then click Save to save the changes to the master configuration.

- **B. Retrieve the certificate from the port:**
  1. Log in to the WebSphere Application Server Administrative Console.
2. Navigate to **Security > SSL certificate and key management > SSL configurations**.

3. Click the appropriate SSL configuration from the list. For example,
   - Stand-alone environments: **NodeDefaultSSLSettings**
   - Clustered environments: **CellDefaultSSLSettings**

   **Clustered environments:** Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

   **Client trust store**
   
   **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

   A. See Secure installation for client signer retrieval.

   B. Run the `retrieveSigners` task from the `wp_profile_root\bin` directory; see `retrieveSigners command` for information. In a deployed environment, you will need to run the `retrieveSigners` task, for any federated node, against the Deployment Manager.

   **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:

   1. Use a text editor to open the `ssl.client.props` file, located in the `wp_profile_root\properties` directory.

   2. Change the `com.ibm.ssl.trustStore` parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter
      
      ```
      com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12
      ```
      
      to use the default trust store.

   3. Save your changes.

2. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

3. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.idap.id`
   - `federated.idap.host`
   - `federated.idap.port`
   - `federated.idap.blindDN`
   - `federated.idap.blindPassword`
   - `federated.idap.idapServerType`
   - `federated.idap.baseDN`

4. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.idap.et.group.objectClasses`
   - `federated.idap.et.group.objectClassesForCreate`
   - `federated.idap.et.group.searchBases`
- `federated.ldap.et.personaccount.objectClasses`
- `federated.ldap.et.personaccount.objectClassesForCreate`
- `federated.ldap.et.personaccount.searchBases`

5. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attribute heading:
   - `federated.ldap.gm.groupMemberName`
   - `federated.ldap.gm.objectClass`
   - `federated.ldap.gm.scope`
   - `federated.ldap.gm.dummyMember`

   Note: See the properties file for specific information about the required parameters and for advanced parameters.

6. Enter a value for the following parameters to enable Secure Socket Layers (SSL):
   - `federated.ldap.sslEnabled`
   - `federated.ldap.sslConfiguration`

   Required parameters:
   - `federated.ldap.certificateMapMode`
   - `federated.ldap.certificateFilter`

   Optional parameters:
   - `federated.ldap.certificateMapMode`
   - `federated.ldap.certificateFilter`

7. Save your changes to the `wkplc.properties` file.

8. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product:
   - `WcmContentAuthorsGroupId`
   - `WcmContentAuthorsGroupCN`

   Note: See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.

9. Run the `ConfigEngine.sh validate-federated-ldap -DWasPassword=passw...ted repository. Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks:
    - Starting and stopping servers, deployment managers, and node agents.

12. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:
      - `Note: See the properties file for specific information about the required parameters and for advanced parameters.`
C. Save your changes to the wkplc.properties file.

D. Run the `ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root` /ConfigEngine directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Run the `ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root` /ConfigEngine directory, to list the names and types of configured repositories.

14. Run the `ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root`/ConfigEngine directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see “Adapting the attribute configuration” for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

15. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

   The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root` /ConfigEngine directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root`/ConfigEngine directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.
E. Stop and restart all necessary servers to propagate your changes.

17. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `ConfigEngine.sh action-express-memberfixer` task, located in the `/PortalServer/wcm/shared/app/config/wcmservices/` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the wkplc.properties file. If the value for <code>federated.realm</code> is empty, use defaultWIMFileBasedRealm as the default value.</td>
</tr>
</tbody>
</table>

18. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

19. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

**Important:**
- Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
- Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `/PortalServer/wcm/shared/app/config/wcmservices/` directory: `ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword` **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.
B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the \( wp\text{-profile}\text{root}/\text{ConfigEngine} \) directory: \texttt{ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid}. \textbf{Important:} You must provide the full distinguished name (DN) for the \texttt{newAdminId} and \texttt{newAdminGroupId} parameters.

\textbf{Additional parameter for stopped servers:} This task verifies the user against a running server instance. If the server is stopped, add the \texttt{-Dskip.ldap.validation=true} parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

20. Optional: \textbf{This step is required in a production environment.} Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: \textit{Deleting the repository}.

If you created your clustered environment then performed the steps in this task, you must now run the \texttt{enable-jcr-security} task on the secondary node. See \textit{Enabling LDAP security after cluster creation} for instructions.

\textbf{Parent topic:} Configuring a federated LDAP user registry on IBM i5/OS in a clustered environment

\textbf{Related tasks}
Starting and stopping servers, deployment managers, and node agents
Enabling LDAP security after cluster creation

\textbf{Related Information}
User IDs and passwords
Adding a database user registry on IBM i5/OS in a clustered environment

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you have WebSphere Application Server Version 7.0.x installed, you must install APAR PM23090 and APAR PM24181 for WebSphere Portal prior to running this task. Clusters with WebSphere Application Server Version 6.1.x do not require these APARs.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_DB.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_DB.properties` helper file.

1. Perform the following steps to create the DB2 for i5/OS database:

**Instructions for setting up databases:** Refer to the appropriate documentation for the type of database you want to set up.

**Consulting your database administrator:** The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

   A. Login to a remote i5/OS session.
   B. Enter the `strsql` command to start the interactive sql session.
   C. Enter the `create schema database_name` command, where `database_name` is the name you want to use for the database.

2. Perform the following steps to define the `DbDriver` and `DbLibrary` parameter values:

   A. Navigate to the following directory: `wp_profile_root/ConfigEngine/properties` directory.
   B. Locate and open `wkplc_dbtype.properties` with any text editor.
   C. Enter a value for the following parameters under the appropriate database type properties heading:
      - `db_type.DbDriver`
      - `db_type.DbLibrary`
   D. Save your changes.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated Database Properties heading:

   **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
5. Change the value for the `com.ibm.SOAP.requestTimeout` parameter to 1000.
   A. Navigate to the following directory: `wp_profile_root/properties`
   B. Locate and open `soap.client.props` with any text editor.
   C. Locate the `com.ibm.SOAP.requestTimeout` parameter and change the value to 1000.
   D. Save and close `soap.client.props`.

6. Perform the following steps in a clustered environment:
   A. Run the `ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=password -` 
      `DDbDomain=federated.db -Db_type.DmgrDbLibrary=local path of the database jars on the Deployment` 
      `Manager -DDmgrNodeName=dmgr_node_name` task from the `wp_profile_root/ConfigEngine` directory to create the local 
      Deployment Manager WebSphere variable used to access the database jars. **Note:** The `db_type` in `db_type` 
      `.DmgrDbLibrary` should be set to the type of database you are using, for example `db2_iseseries`. The `local path of` 
      `the database jars on the Deployment Manager` should be one of the following options:

      `DB2 for i5/OS Type 2 driver:/QIBM/ProdData/Java400/ext/db2_classes.jar`
      `DB2 for i5/OS Type 4 driver:/QIBM/ProdData/HTTP/Public/jt400/lib/jt400.jar`

   B. Run the following task. Include each node name as a comma separated list in the command:
      **Running the task:** You do not have to run this task more than once. You can run this task from any node in the
      cluster.

      1. Set the property value for `federated.db.DbType` if using a database user registry and set the property value for
         `la.DbType` if using a property extension database in the wkplc.properties file.
      2. Run the `ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=password -` 
         `DDbDomain=federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the` 
         `database jars` task from the `wp_profile_root/ConfigEngine` directory on each node to create the variable used to
         access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in
         the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to
         the type of database you are using, for example `db2`.

         `DB2 for i5/OS Type 2 driver:/QIBM/ProdData/Java400/ext/db2_classes.jar`
         `DB2 for i5/OS Type 4 driver:/QIBM/ProdData/HTTP/Public/jt400/lib/jt400.jar`

   C. Stop and restart all necessary servers to propagate your changes.

   7. Run the `ConfigEngine.sh wp-create-db -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` 
      directory, to add a database user registry to the default federated repository. **Note:** Users who are not in an LDAP do 
      not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and 
      then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who 
      sign up using the Self Care portlet do not have awareness.
8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

      C. Save your changes to the `wkplc.properties` file.

      D. Run the `ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

      E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the `ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

    If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

**Parent topic:** Configuring the default federated repository on IBM i5/OS in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Adding realm support on IBM i5/OS in a clustered environment

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. **Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.**
   - **Required:** Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
     - realmName
     - securityUse
     - delimiter
     - addBaseEntry
   - **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

2. **Save your changes to the wkplc.properties file.**

3. **Run the ConfigEngine.sh wp-create-realm -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add a new realm to the Virtual Member Manager configuration.**
   - **Important:** To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the wkplc.properties file with the base entry information and rerun the wp-create-realm task. Repeat these steps until all realms are created.

4. **Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.**

5. **Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading and then save your changes.**
   - **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
     - realmName
     - realm.personAccountParent
     - realm.groupParent
     - realm.orgContainerParent

6. **Run the ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to update the default parents per entity type and realm.**
   - **Important:** Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types.
and realms.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:
   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
      - realmName
      - addBaseEntry
   C. Save your changes to the wkplc.properties file.
   D. Run the ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add additional LDAP base entries to the realm configuration.
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:
    A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.
    B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.
    C. Create a new group in the Manage Users and Groups portlet to replace the current group.
    D. Run the ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task, from the wp_profile_root/ConfigEngine directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group. Important: You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

    Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.
    E. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
    F. Run the ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task to replace the old WebSphere Portal administrative user ID and group ID with the new user and group. Important: You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.

    Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.
    G. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

11. Optional: Perform the following steps to set the realm you created as the default realm: Remember: Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the wp-query-realm-baseentry task to see what base entries are part of the default realm. If the default realm is missing
the base entry, run the `wp-add-realm-baseentry` task to add the base entry to the default realm.
A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
B. For `defaultRealmName`, type the `realmName` property value you want to use as the default realm.
C. Save your changes to the `wkplc.properties` file.
D. Run the `ConfigEngine.sh wp-default-realm -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set this realm as the default realm.
E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:
A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
B. For `realmName`, type the name of the realm you want to query.
C. Save your changes to the `wkplc.properties` file.
D. Run the `ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:
A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
B. Enter a value for `realmName` or leave blank to update the default realm.
C. Save your changes to the `wkplc.properties` file.
D. Run the `ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.
E. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring the default federated repository on IBM i5/OS in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Adapting the attribute configuration

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. **Querying the defined attributes on IBM i5/OS**
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. **Adding attributes on IBM i5/OS in a clustered environment**
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. **Mapping attributes on IBM i5/OS in a clustered environment**
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. **Removing attributes**
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Parent topic: Choosing your user registry model on IBM i5/OS in a clustered environment

Related tasks
- Adding an LDAP user registry on IBM i5/OS
- Adding an LDAP user registry over SSL on IBM i5/OS
- Configuring a stand-alone LDAP user registry on IBM i5/OS
Configuring a stand-alone LDAP user registry over SSL on IBM i5/OS
Querying the defined attributes on IBM i5/OS

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `ConfigEngine.sh wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (**PersonAccount**) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on IBM i5/OS in a clustered environment
**Adding attributes on IBM i5/OS in a clustered environment**

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file:

   **Table 1. Steps for installing the .ear file by environment**

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone environment</td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the wp_profile_root/ConfigEngine directory. Run the ConfigEngine.sh wp-la-install-ear -DWasPassword=password task.</td>
</tr>
<tr>
<td>Clustered environment</td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the wp_profile_root/ConfigEngine directory on the primary node. Run the ConfigEngine.sh wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name task. Where node_name is the name of the node where the deployment manager resides; you can find the node_name value in the WebSphere Application Server Administrative Console under <strong>System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name</strong>.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

3. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

4. Enter a value for the following required parameters in the wkplc.properties file under the VMM Property Extension Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - la.providerURL
   - la.propertyName
   - la.entityTypes
   - la.dataType
   - la.multiValued

5. Save your changes to the wkplc.properties file.
6. Run the `ConfigEngine.sh wp-add-property -DWasPassword=password` task to add the attribute to the user registry.

**Note**: This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

**Remember**: If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents*.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Adapting the attribute configuration

**Previous topic:** Querying the defined attributes on IBM i5/OS

**Next topic:** Mapping attributes on IBM i5/OS in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Mapping attributes on IBM i5/OS in a clustered environment

After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

Perform the following steps to map attributes between WebSphere Portal and your LDAP server; if you have multiple LDAP servers, you will need to perform these steps for each LDAP server:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
2. Enter a value for one of the following sets of parameters in the wkplc.properties file to identify your LDAP server:
   - **Note:** Make sure you use the same values you used to configure your LDAP server.
   
   **Table 1. Identifying your LDAP server in the wkplc.properties file.**

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>The following parameters are found under the LDAP attribute configuration heading:<strong>Note:</strong> See the properties file for specific information about the required parameters and for advanced parameters. standalone.ldap.id standalone.ldap.host standalone.ldap.port standalone.ldap.sslEnabled standalone.ldap.bindDN standalone.ldap.bindPassword standalone.ldap.baseDN</td>
</tr>
<tr>
<td>Federated</td>
<td>The following parameters are found under the VMM Federated repository properties heading:<strong>Note:</strong> See the properties file for specific information about the required parameters and for advanced parameters. federated.ldap.id federated.ldap.host federated.ldap.port federated.ldap.sslEnabled federated.ldap.bindDN federated.ldap.bindPassword federated.ldap.baseDN</td>
</tr>
</tbody>
</table>

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:
   - **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   
   **Table 2. Task to check that all defined attributes are available in the configured LDAP user registry.**

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory.</td>
</tr>
<tr>
<td>Federated</td>
<td>ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory.</td>
</tr>
</tbody>
</table>

4. Open the ConfigTrace.log file, located in the wp_profile_root/ConfigEngine/log directory, to review the following output for the **PersonAccount** and **Group** entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the `uid`, `cn`, `firstName`, `sn`, `preferredLanguage`, and `ibm-primaryEmail` attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

6. Enter a value for one of the following sets of parameters in the `wkplc.properties` file to correct any issues found in the config trace file: Table 3. Parameters to define in the wkplc.properties file to correct any issues found in the config trace file.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
</table>
| Stand-alone     | The following parameters are found under the LDAP attribute configuration heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.  
|                 | `standalone.ldap.idstandalone.ldap.attributes.nonSupportedstandalone.ldap.attributes.mapping.ldapName=mail, title`  
|                 | `standalone.ldap.attributes.mapping.portalName=ibm-primaryEmail, ibm-jobTitle`  
|                 | `standalone.ldap.attributes.mapping.entityTypes=PersonAccount, Group` |
7. Save your changes to the wkplc.properties file.

8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

   Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>ConfigEngine.sh wp-update-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory</td>
</tr>
<tr>
<td>Federated</td>
<td>ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory</td>
</tr>
</tbody>
</table>

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:

    A. Enter a value for the following required parameters in the wkplc.properties file: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

       - `user.attributes.required`
       - `user.attributes.nonsupported`

    B. Save your changes to the wkplc.properties file.

    C. Run the `ConfigEngine.sh wp-update-attribute-config` -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory.

    D. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the enable-jcr-security task on the secondary node. See Enabling LDAP security after cluster creation for instructions.
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database: **Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.
   A. Open the tool you use to edit your database.
   B. Verify that your attribute name is available in the LAPROP table.
   C. Delete the required attributes from the LAPROP table.
   D. Open the `wimxmlextenstaion.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/model` directory.
   E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   F. Save your changes to the `wimxmlextenstaion.xml` file.
   G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/config` directory.
   H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <config:propertiesNotSupported name="attribute_name"/>
   ```
   I. Save your changes to the `wimconfig.xml` file.
   J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:
   A. Open the `wimxmlextenstaion.xml` file.
   B. Locate and delete the `propertySchema` definition for the attributes you previously added:

   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```
   C. Save your changes to the `wimxmlextenstaion.xml` file.
   D. Open the `wimconfig.xml` file.
   E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:

   ```xml
   <config:attributes name="attribute_name" propertyName="property_name">
     <config:entityTypes>PersonAccount</config:entityTypes>
   </config:attributes>
   ```
   F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

Parent topic: Adapting the attribute configuration
Previous topic: Mapping attributes on IBM i5/OS in a clustered environment
Preparing additional nodes on IBM i5/OS

After installing and configuring your primary node, you can create your secondary nodes. You must install IBM® WebSphere® Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Installing a secondary node after migrating from previous version

Perform the following tasks to prepare your secondary node:

1. **Installing WebSphere Portal on i5/OS on the additional nodes**
   Install IBM WebSphere Portal on your secondary nodes to create a highly available and scalable environment.

2. **Adding additional nodes to the cluster on i5/OS**
   After installing IBM WebSphere Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

3. **Optional: Adding vertical cluster members to a static cluster on IBM i5/OS**
   You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

**Parent topic:** Setting up a cluster on IBM i5/OS

**Previous topic:** Configuring WebSphere Portal to use a user registry on IBM i5/OS in a clustered environment

**Next topic:** Rendering documents on IBM i5/OS
Installing WebSphere Portal on i5/OS on the additional nodes

Install IBM® WebSphere® Portal on your secondary nodes to create a highly available and scalable environment.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. Note: If you plan to use IBM WebSphere Application Server Version 7.0, you must purchase and install it before installing WebSphere Portal on the existing WebSphere Application Server Version 7.0 instance.

Perform the following steps to install WebSphere Portal:

1. Type ping yourserver.yourcompany.com on a command line to verify that your fully qualified host name is properly configured.
2. Setup a static IP address on the server where you will install WebSphere Portal.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - Restriction: Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - Important: Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities

4. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

   **Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

   **Restriction:** When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graphical user Interface</td>
<td>install400.bat Optional attribute: WebSphere Application Server profiles and configurations are performed with the Classic 64-bit JVM by default. To install and configure the portal profile with J9 32-bit JVM, add the -W enableClassicJVM.active=false attribute to your installation command.</td>
</tr>
</tbody>
</table>
5. Perform the following steps if you migrated from a previous version of WebSphere Portal:

A. Log on to the WebSphere Application Server Administrative Console.

C. Click WP Identification.

D. Click Custom properties.

E. If applicable, note the location of the LpidToGupidMapping.properties file.

F. If the LpidToGupidMapping.properties file exists on the primary node, copy the file to the same location on the secondary node.

Parent topic: Preparing additional nodes on IBM i5/OS

Next topic: Adding additional nodes to the cluster on i5/OS

Related concepts

Installation methods
IBM Support Assistant Lite for WebSphere Portal
Adding additional nodes to the cluster on i5/OS

After installing IBM® WebSphere® Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

- Prerequisites
  - Installing WebSphere Portal on i5/OS on the additional nodes

Perform the following steps to add the secondary node to the cluster:

1. Perform the following steps on the secondary node to access your database server:
   - Note: All properties files are located in the \wp_profile_root\ConfigEngine\properties directory.
     A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes.
     B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
     C. Set all database properties in the wkplc_dbtype.properties and wkplc_comp.properties files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. ConfigEngine.sh validate-database-driver
      DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   B. ConfigEngine.sh validate-database-connection -DWasPassword=password
      DTransferDomainList=release,customization,community,jcr,feedback,likeminds

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the profiles/wp_profile/ConfigEngine/properties directory of the secondary node:
   - Note: Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
     A. Verify that WasUserid is set to your deployment manager administrator ID.
     B. Verify that WasPassword is set to your deployment manager administrator password.
     C. Verify that PortalAdminId is set to your WebSphere Portal administrator ID.
     D. Verify that PortalAdminPwd is set to your WebSphere Portal password.
     E. Verify that WasRemoteHostName is set to the fully qualified host name of the deployment manager.
     F. Verify that WasSoapPort is set to the SOAP port that the deployment manager is using; the default value is 8879.
     G. Verify that PrimaryNode is set to false.
     H. Verify that ClusterName is set to the primary node’s ClusterName.

4. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the secondary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.

5. Run the ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the secondary node.

6. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.

  **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `ConfigEngine.sh wp-node-prep-vmm-db-secured-environment` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. **Note:**`VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

```
DB2 for i5/OS Type 2 driver:/QIBM/ProdData/Java400/ext/db2_classes.jar

DB2 for i5/OS Type 4 driver:/QIBM/ProdData/HTTP/Public/jt400/lib/jt400.jar
```

7. Run the `ConfigEngine.sh cluster-node-config-post-federation` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the `ServerName` parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

8. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal Program ID and password to match an administrative user defined in the cell’s user registry. Run the `ConfigEngine.sh wp-change-portal-admin-user` task from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

  **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

  **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

  **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

  **Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user` task.

  **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

  **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

9. Optional: Open the `wkplc.properties` file and change the `ServerName` parameter from the default `WebSphere_Portal_nodename` value to a value that meets your business needs. Do not change the parameter to `WebSphere_Portal` as this is the primary node value.

10. Run the `ConfigEngine.sh cluster-node-config-cluster-setup` task to add the node to your cluster.
11. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

12. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select **Environment > WebSphere Variables**.
   C. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server.
   D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select **System Administration > Nodes**.
      2. Select the node that you want to synchronize from the list.
      3. Click **Full Resynchronize**.
   G. Log off of the deployment manager administrative console.

13. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Preparing additional nodes on IBM i5/OS  
**Previous topic:** Installing WebSphere Portal on i5/OS on the additional nodes  
**Next topic:** Adding vertical cluster members to a static cluster on IBM i5/OS

**Related tasks**
Deleting passwords from properties files
Adding vertical cluster members to a static cluster on IBM i5/OS

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

- **Prerequisites**
  - Installing WebSphere Portal on i5/OS on the additional nodes
  - Adding additional nodes to the cluster on i5/OS

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Log into the deployment manager administrative console.
2. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - For **WebSphere Application Server Version 6.1**: Click **Servers > Clusters** in the console navigation tree, select the cluster name, and then click **Cluster members** from the list of additional properties.
   - For **WebSphere Application Server Version 7.0**: Click **Servers > Clusters > WebSphere application server clusters > cluster_name > Cluster members**.
3. Click **New** to create the cluster member.
   - Define the name of cluster member. **Note:** Do not use spaces in the cluster member name.
   - Select an existing node where IBM® WebSphere® Portal is installed.
   - Check the box **Generate Unique HTTP Ports**.
   - Click **Apply** and then click **Next** to view the summary.

**Important:** If you are not using an external Web server in your clustered environment, you must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the `default_host` virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See **Configuring virtual hosts** for information.

4. Click **Finish**, and save the changes.
   - The new cluster topology can be viewed from the **Servers > Cluster Topology** view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the **Servers > Clusters > Cluster Topology** view.
   - The **Servers > Application Servers** view will list the new server cluster members. If using WebSphere Application Server Version 7.0, the **Servers > Server Types > WebSphere application servers** view will list the new server cluster members.

5. Perform the following steps to enable cache replication:
   - From the deployment manager Administrative Console, navigate to **Servers > Application servers** and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to **Servers > Server Types > WebSphere application servers** and then click the new vertical cluster member(s).
   - Click **Dynamic cache service** under **Container services**.
   - Change **Cache size** to **3000** entries.
   - Check the **Enable cache replication** check box.
   - Select **NOT_SHARED** from the **Replication type** drop-down menu.
   - Click **OK**.
   - Click **Save** to save your changes to the master configuration.

6. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   - Run the `ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical`
Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.

B. Select **Environment > WebSphere Variables**.

C. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server.

D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

8. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click **Save** on the task bar, and save your administrative configuration.
   B. Select **System Administration > Nodes**, select the node from the list, and click **Full Resynchronize**.

9. Regenerate the Web server plug-in.
   A. Regenerate the Web server plug-in using the deployment manager administrative console.
   B. If you are using a remote Web server, copy the updated plug-in configuration file (**plugin-cfg.xml**) to the Web server's plug-in configuration directory.

10. Stop and start the Web server.
Rendering documents on IBM i5/OS

In order to enable document preview functionality for IBM® Lotus Web Content Management and the Common Mail portlet, you must set up an HTML rendering server to work with WebSphere Portal. Because IBM i5/OS does not contain native graphics support, you must install additional fonts to perform the document conversion required by these functions. Document conversion enables WebSphere Portal to convert documents produced by commonly used office programs into Web pages, so that they can be viewed and searched by users online. The additional fonts include an HTML rendering server known as X virtual frame buffer for the X server.

Before you begin, you must have:
- A WebSphere Portal profile running on your IBM i5/OS system; record the name of your WebSphere Portal profile for future reference.
- OS/400 - Additional Fonts (5722SS1, Option 43) or OS/400 - Additional Fonts (5761SS1, Option 43) installed.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Preparing additional nodes on IBM i5/OS

Perform the following tasks on each WebSphere Portal node to render documents on IBM i5/OS:

**Note:** The HTML rendering server (X virtual frame buffer for X server) that you associate with your WebSphere Portal profile should only be used for WebSphere Portal. Using the HTML rendering server with other applications may cause problems.

1. Configuring an HTML rendering server on IBM i5/OS
   
   After you have installed OS/400 - Additional Fonts (5722SS1, Option 43), which is for Version 5R4, or OS/400 - Additional Fonts (5761SS1, Option 43), which is for Version 6R1, on your IBM i5/OS system, an HTML rendering server (X virtual frame buffer for X server) is present. You must select a display number for the HTML rendering server.

2. Optional: Associating an HTML rendering server with WebSphere Portal
   
   After selecting a display number for the HTML rendering server (X virtual frame buffer for X server), you must associate this server with the installed IBM WebSphere Portal profile.
Configuring an HTML rendering server on IBM i5/OS

After you have installed OS/400 - Additional Fonts (5722SS1, Option 43), which is for Version 5R4, or OS/400 - Additional Fonts (5761SS1, Option 43), which is for Version 6R1, on your IBM® i5/OS system, an HTML rendering server (X virtual frame buffer for X server) is present. You must select a display number for the HTML rendering server.

Perform the following steps to configure an HTML rendering server:

1. If the QShell Interpreter is running, perform the following commands on the IBM i5/OS command line to stop it:
   - QSH
   - Press F3

2. Type `CALL QP2TERM` on the command line to start the OS/400 Portable Application Solutions Environment (OS/400 PASE) console.

3. Type `ps gaxuw | grep Xvnc ; ps gaxuw | grep vfb` on the command line to list all active HTML rendering servers:
   
   **Note:** If other rendering servers are already active, you may see output such as this (the number following the colon is the display number already in use):
   
   ```
   v2kea554 40571 0.0 0.0 12484 0 - A Jul 13 4:08
   /QOpenSys/QIBM/ProdData/DeveloperTools/vnc/Xvnc :6 -desktop X -httpd
   ```

4. Select any number from 1 to 99 that is not in use.

5. Type `SBMJOB CMD(CALL PGM(QP2SHELL) PARM(`/usr/bin/X11/X' '-vfb' '':N')) JOB(XVFB) JOBQ(QSYSNOMAX) ALWMLTTHD(*YES)` on the command line to start the HTML rendering server, where \(N\) is the display number.

6. Verify that the HTML rendering server is started by repeating the prior steps to start PASE and list the active servers, confirming that an HTML rendering server with your display number is in the list.

**Parent topic:** Rendering documents on IBM i5/OS

**Next topic:** Associating an HTML rendering server with WebSphere Portal
Associating an HTML rendering server with WebSphere Portal

After selecting a display number for the HTML rendering server (X virtual frame buffer for X server), you must associate this server with the installed IBM® WebSphere® Portal profile.

- Prerequisites
  - Configuring an HTML rendering server on IBM i5/OS

Perform the following steps to associate the HTML rendering server (X virtual frame buffer for X server) with WebSphere Portal:

1. Log into the IBM WebSphere Application Server administrative console.
2. Log into the IBM WebSphere Application Server administrative console. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - Click New.
   - In the Name field type DISPLAY.
   - In the Value field type host_name:n, where host_name is the TCP/IP host name of your system and n is the display number of the HTML rendering server. (Example: 'mysystem.xland.company.com:1').
3. Click OK.
4. Save your changes to the master WebSphere Application Server configuration file.
5. Perform the following steps to stop and restart the server1 and WebSphere_Portal servers, where server1 is the name of the WebSphere Application Server and WebSphere_Portal is the name of the WebSphere Portal server:
   A. Open a command prompt and change to the wp_profile_root/bin directory.
   B. Enter the stopServer server1 -username admin_userid -password admin_password command to stop the WebSphere Application Server.
   C. Enter the stopServer WebSphere_Portal -username admin_userid -password admin_password command to stop the WebSphere Portal server.
   D. Enter the startServer server1 command.
   E. Enter the startServer WebSphere_Portal command.
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Preparing additional nodes on IBM i5/OS

**Base Portal Tuning Scenarios**

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services

Configuring search in a cluster on i5/OS

IBM® WebSphere® Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Preparing additional nodes on IBM i5/OS
  - Tune your servers

- **Configuring Portal Search in a cluster on i5/OS**
  To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM WebSphere Application Server node that is not part of the IBM WebSphere Portal cluster.

- **Configuring JCR search in a cluster on i5/OS**
  To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

Parent topic: Setting up a cluster on IBM i5/OS
Previous topic: Tune your servers
Next topic: Setting up multiple clusters on IBM i5/OS
Configuring Portal Search in a cluster on i5/OS

To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM® WebSphere® Application Server node that is not part of the IBM WebSphere Portal cluster.

To install and configure the search service remotely, perform the following tasks:

1. Install and configure the search service to work remotely, that is, on a remote WebSphere Application Server node which is not part of the portal cluster. You can provide the remote search service either as an EJB or as a Web service via SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server node. For details about how to do this, refer to the WebSphere Application Server documentation.

2. Configure the search portlets for remote search service so that they access the remote server accordingly.

**Notes:**

1. If you have configured a remote search service for a portal cluster, you need to configure the default location for search collections to a directory on the remote server that has write access.

2. The portal site default search collection is created only once at the first time when an administrator selects the search administration portlet Manage Search. If this occurred _before_ you configure the portlet for remote search, then the default portal site search collection is only available on the primary node of the cluster, but not on the remote server. In this case you need to recreate the portal site collection to make it available for search on all nodes of the cluster.

**Parent topic:** Configuring search in a cluster on i5/OS

**Related concepts**

Planning and preparing for Portal Search

Using remote search service

**Related tasks**

Configuring Portal Search for remote search service

Configuring the Search and Browse portlet for remote search service

Configuring the default location for search collections

Creating or resetting the portal site collection

Configuring the primary node to communicate with the deployment manager on i5/OS

Configuring a remote search service
Configuring JCR search in a cluster on i5/OS

To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

Create a shared directory called `jcr/search` on a server in the network and ensure that each node in the cluster and the Deployment Manager has network access to the directory.

**Note:** If you are creating content in a clustered environment using the authoring portlet provided with Web Content Management, additional configuration steps are required to enable content created by these content features to be searchable in a cluster.

Perform the following steps on each server in the cluster to configure Search in a clustered environment:

1. Edit the `icm.properties` file, located in the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory.
2. Change the value of the `jcr.textsearch.indexdirectory` property to the shared directory; for example,
   
   `jcr.textsearch.indexdirectory=\\your_server\your_share\jcr\search`

   You can specify the shared directory value in one of the following formats: *Table 1. The format for the shared directory.*

<table>
<thead>
<tr>
<th>Format</th>
<th>Shared directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal Naming Convention (UNC) format</td>
<td><code>\\your_server\your_share\jcr\search</code> Example: <code>\\hostname.example.com\share\jcr\search</code></td>
</tr>
<tr>
<td>Mounted resource format (with forward slashes)</td>
<td><code>/your_share/jcr/search</code> For example: <code>/mnt/jcr/search</code></td>
</tr>
</tbody>
</table>

**Important:** This format requires that you mount the shared directory to the local server (for example, through a mapped network drive or a mounted directory). When using the mounted resource format, always use forward slashes instead of back slashes, regardless of the native operating system path format.

3. Required: Perform the following steps to delete the default search collections from the Manage Search portlet:

   A. Log on to WebSphere Portal as an administrator.
   B. Click **Administration > Search Administration > Manage Search**.
   C. Click **Search Collections**.
   D. Click the **Delete Collection** icon for the **Portal Content** search collection.
   E. Click **OK**.
   F. Restart the WebSphere_Portal server.
   G. Go to the Manage Search portlet and confirm that the **Portal Content** search collection was deleted.

**Parent topic:** Configuring search in a cluster on i5/OS
Setting up multiple clusters on IBM i5/OS

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM® WebSphere® Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

Before attempting alternative approaches for building multiple portal-based clusters within a single cell, please contact IBM.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Preparing additional nodes on IBM i5/OS
  - Tune your servers

- **Installing multiple clusters in a single cell on IBM i5/OS**
  Create a new, independent IBM WebSphere Portal cluster in a cell where a WebSphere Portal cluster already exists.

- **Routing requests across clusters on IBM i5/OS**
  The HTTP Server plug-in that comes with IBM WebSphere Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.
Installing multiple clusters in a single cell on IBM i5/OS

Create a new, independent IBM® WebSphere® Portal cluster in a cell where a WebSphere Portal cluster already exists. In the following steps, Cluster A will be used to describe the existing cluster. Portal B will be used to describe the new server profile that will be the basis for the new cluster definition, Cluster B. Perform the following steps to install multiple clusters in a single cell:

1. Upgrade Cluster A, including the Deployment Manager node, to the current, supported hardware and software levels and to the current version of IBM WebSphere Portal.

2. Install and configure Portal B; see the "Preparing the primary node" topic for the appropriate operating system for details. Important: Maintain the same number of data sources with identical names to the Cluster A data sources so that data source bindings in the applications can be resolved on every cluster in which they run. If implementing database sharing across the clusters, the above statement refers to both the shared and non-shared domains; all domains should use the same names.

3. Optional: Using the same database user ID and password for each identically named domain/data source will allow the existing JAAS AuthenticationAliases to be functional. If unique database user ID and password are required, additional manual configuration is needed to create new JAAS AuthenticationAliases for each data source and map these accordingly. On the primary node of Cluster A, run the ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the new JAAS AuthenticationAliases. Where authDomainList is set to a list of domains which use unique database user ID and passwords and those domain properties are set correctly in the wkplc_comp.properties file, including user ID and password.

4. Optional: If necessary, upgrade Portal B to the current cumulative fix.

5. Run the ConfigEngine.sh mapped-app-list-create -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to build an inventory of Portal B enterprise applications and portlets.

6. Stop the server1 and WebSphere_Portal servers on Portal B and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   - Set WasSoapPort to the deployment manager's port.
   - Set WasRemoteHostName to the full host name of the deployment manager.

7. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading. Important: Ensure that you set WasUserId and WasPassword to the Deployment Manager user ID and password.

8. Run the ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=password task from the wp_profile_root/ConfigEngine directory of the primary node.

9. Run the ConfigEngine.sh map-apps-to-server -DWasPassword=password task to determine which applications from the inventory list are no longer mapped to Portal B. The task uses the application profiles already in the cell to restore the mappings. Wait 30 minutes after running this task to allow all EAR files to expand before proceeding to the next step.

10. Perform the following steps to federate Portal B into the deployment manager cell:
A. Ensure that all database parameters are correctly set, including passwords, in the `wkplc_comp.properties` and `wkplc_dbtype.properties` files.

B. Run the `ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

C. After running the `cluster-node-config-post-federation` task, wait at least 30 minutes to allow all EAR files to expand.

D. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere _Portal_ server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

E. From the administrative console, click *System Administration > Node Agents.*

F. Check the box next to the required node agent and then click Restart.

G. Stop and restart the deployment manager.

H. Stop and restart the WebSphere _Portal_ server on Portal B

11. Restart the WebSphere _Portal_ server on Cluster A. Verify that Cluster A is functionally intact by spot checking pages and portlets and then verify that Portal B is functionally intact by spot checking pages and portlets that you deployed into Portal B before it was federated. Any discrepancies or errors should be corrected now before continuing. **Note:** If Portal B is using a non-default Portal server administrative ID, not *wpsadmin*, the server will not be functional until the cluster configuration is complete and the Portal administrative ID has been configured to match the Cells security settings.

12. Perform the following steps to define a cluster using Portal B as the basis:

A. Run the `ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task.

B. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:
   - Recommended remote distributed installation
   - Local distributed installation
   - Setting up multiple clusters on IBM i5/OS

C. Perform the following steps to access the Web Content Management content through an external Web server:
   1. Log on to the deployment manager administrative console.
   2. Select Environment > WebSphere Variables.
   3. From the Scope drop-down menu, select the Node=node_name, Server=servername option to narrow the scope of the listed variables, where Node=node_name is the node that contains the application server.
   4. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   5. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

D. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere _Portal_ servers.
E. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:
- Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup

13. Install any additional nodes to the cell to support additional cluster members for Cluster B identically to the primary node, and then federate as them as secondary nodes and define as cluster members on these nodes. For information about adding additional nodes navigate to Installing WebSphere Portal > Setting up WebSphere Portal > Setting up a clustered production environment > Setting up a production environment on i5/OS > Preparing additional nodes on i5/OS. You can add additional nodes and/or vertical clusters.

14. Restart the server1 and WebSphere_Portal servers on Cluster A and Cluster B.

15. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See “Deleting passwords from properties files” under Related tasks for information.

Installation of Cluster B is complete. It is now an independent cluster from Cluster A, which means that Cluster B can have its own configuration, set of end-user portlets, and target community. Any applications that are common between Cluster A and Cluster B are most likely infrastructure or related to administration, and special care needs to be taken to preserve their commonality between clusters and correct maintenance levels.

Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Routing requests across clusters on IBM i5/OS

The HTTP Server plug-in that comes with IBM® WebSphere® Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

An important consideration in a multiple cluster environment is ensuring that all subsequent HTTP requests for an end user are routed to the same cluster that processed the first HTTP request. The WebSphere Portal login processing depends upon preserving this cluster affinity during this initial time until the user has successfully logged in and session cookies maintain affinity. In order to guarantee that affinity is preserved during login, set the Navigator Service `public.session` parameter to a value of true. Refer to “Portal Configuration Services” for information on how to configure this parameter.

Parent topic: Setting up multiple clusters on IBM i5/OS
Sharing database domains between clusters on i5/OS

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM® WebSphere® Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

- Prerequisites
  - Preparing prerequisite and corequisite software on IBM i5/OS
  - Preparing your IBM i5/OS
  - Preparing the primary node on IBM i5/OS
  - Preparing additional nodes on IBM i5/OS
  - Tune your servers

Important: JCR domains and release domains cannot be shared between different Web Content Management clusters or servers. Each distinct cluster or server in your Web Content Management system must use a separate JCR or release domain. For example:

<table>
<thead>
<tr>
<th>Development Server</th>
<th>Authoring Cluster</th>
<th>Staging Server</th>
<th>Delivery Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>JCR Domain 1</td>
<td>JCR Domain 2</td>
<td>JCR Domain 3</td>
<td>JCR Domain 4</td>
</tr>
<tr>
<td>Release Domain 1</td>
<td>Release Domain 2</td>
<td>Release Domain 3</td>
<td>Release Domain 4</td>
</tr>
</tbody>
</table>

Perform the following steps to share database domains when setting up an environment with multiple clusters:

1. Set up the first cluster (referred to as Cluster A in these instructions).
2. Determine which database domains you want to share with any other clusters in the environment.
3. Install the primary node of the next cluster (Cluster B), and perform the following steps to configure the node to use the shared database domains.
   A. Perform a partial database transfer of the database domains that you are not sharing. For example, if you are sharing only the Customization and Community domains, you would transfer the remaining domains to the database you are using for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.
4. Continue setting up the primary node as described in the cluster instructions.
5. Install the secondary node of Cluster B, and perform the following steps to configure the node to use the shared database domains.
   A. For those database domains that you are not sharing between clusters, reconfigure the domains to connect to the database domains you are using for Cluster B. As in the example for the primary node, if you are sharing only the Customization and Community domains, reconfigure the remaining domains on the secondary node to use the domains of the primary node for Cluster B.
B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.

6. Continue setting up the secondary node as described in the cluster instructions.

**Parent topic:** Setting up a cluster on IBM i5/OS

**Previous topic:** Setting up multiple clusters on IBM i5/OS

**Related tasks**

Connecting to existing database domains
Setting up a cluster on Linux

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Prerequisites**
  - Technotes for installation and configuration issues

Perform the following steps to set up your production environment on Linux:

1. **Preparing prerequisite and corequisite software on Linux**
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your Linux operating system**
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on Linux**
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Choosing the type of cluster to create on Linux**
   If you installed a IBM WebSphere Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

5. **Preparing a remote Web server when portal is installed on Linux**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Configuring WebSphere Portal to use a user registry on Linux in a clustered environment**
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

7. **Preparing additional nodes on Linux**
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

8. **Tune your servers**
   Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

9. **Configuring search in a cluster on Linux**
   IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.
10. **Setting up multiple clusters on Linux**

   The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

11. **Sharing database domains between clusters on Linux**

   To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

*Parent topic:* Setting up a cluster
Preparing prerequisite and corequisite software on Linux

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. **Preparing the WebSphere Application Server Deployment Manager on Linux**
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. **Preparing a remote Web server when portal is installed on Linux**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

**Parent topic:** Setting up a cluster on Linux  
**Next topic:** Preparing your Linux operating system
Preparing the WebSphere Application Server Deployment Manager on Linux

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Set the file descriptor limit to 10240; for example, ulimit -n 10240.
2. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command: cd_root/Linux/architecture/ifpackage/WAS/install, where cd_root is the root directory of the disc and architecture is the system's processor architecture.
3. Choose one of the following options to create a default deployment manager profile: Important: While creating the default deployment manager profile, enable administrative security. If you use the Profile Management Tool, check the enable administrative security check box. If you use the manageprofile command, add the enableAdminSecurity=true parameter to the command line.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile Management Tool</td>
<td>See Creating a deployment manager profile for information.</td>
</tr>
<tr>
<td>manageprofile commands</td>
<td>See manageprofile commands for information. Note: If you have a 64-bit environment, only the manageprofiles command is supported when creating profiles.</td>
</tr>
</tbody>
</table>

4. Run the following command to start the deployment manager: ./startManager.sh, from the dmgr_profile_root/bin directory.
5. Use the following URL to launch the network deployment administrative console: http://dmgr_hostname:9060/ibm/console, where dmgr_hostname is the fully qualified host name for the WebSphere Application Server Network Deployment.
6. Log into the deployment manager administrative console.
7. Increase the HTTP connection timeouts for the deployment manager.
   A. Click System Administration > Deployment Manager > Web container transport chains.
   B. Increase the timeout values. For the WCInboundAdmin and WCInboundAdminSecure entries listed in the web container transport chains section, complete the following steps to increase the timeout values:
      1. Click HTTP Inbound Channel.
      2. Change the Read timeout value to 180.
      3. Change the Write timeout value to 180.
      4. Save the configuration changes.
8. Change the timeout request period for the Java Management Extensions (JMX) connector.
   A. Click System administration > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties.
   B. Select the requestTimeout property, and increase the value from 600 to 6000.
   C. Save the configuration changes.
9. Update the maximum Java heap size used by the deployment manager:
   A. Click System administration > Deployment manager > Java and Process Management > Process Definition >
Java Virtual Machine.

B. Update the value in the Maximum Heap Size field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management Product Documentation page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.

C. Click **OK** and then save your changes.

10. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - **Note:** If security is not enabled on your deployment manager, see Enabling security for information before performing this step.
   - For **WebSphere Application Server Version 6.1**: Click Security > Secure administration, applications and infrastructure and select Enable Application Security. Then save the configuration changes.
   - For **WebSphere Application Server Version 7.0**: Click Security > Global security and select Enable Application Security. Then save the configuration changes.

11. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:
   A. Click **Users and Groups** > **Manage Users**.
   B. Click **Create**.
   C. Type the information for the WebSphere Portal administrative users; for example wpsadmin and wpsbind, and then click **Create**.
   D. Click **Users and Groups** > **Manage Groups**.
   E. Click **Create**.
   F. Type wpsadmins as the name of the WebSphere Portal administrative group and then click **Create**.
   G. Click the group you just created; for example wpsadmins.
   H. Click the **Members** tab.
   I. Click **Add Users**.
   J. Search for the users.
   K. Select the users you want to add to the group.
   L. Click **Add** to add the users to the group.
   M. Click **Close** when you are done adding users to the group.
   N. Log out of the administrative console.

13. Run the following tasks to stop and restart the deployment manager:
   A. `./stopManager.sh -username admin_userid -password admin_password`, from the dmgr_profile_root\bin directory
   B. `./startManager.sh`, from the dmgr_profile_root\bin directory

**Parent topic:** Preparing prerequisite and corequisite software on Linux

**Next topic:** Preparing a remote Web server when portal is installed on Linux
Preparing a remote Web server when portal is installed on Linux

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on Linux
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `On`; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server documentation</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>See the appropriate Apache Server documentation</td>
<td>AllowEncodedSlashes directives</td>
</tr>
</tbody>
</table>

4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

   **If using WebDAV:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

   **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.
Preparation your Linux operating system

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- Prerequisites
  - Preparing prerequisite and corequisite software on Linux

Perform the following steps to prepare your Linux machine:

1. Perform the steps to prepare your operating system for the IBM WebSphere Application Server installation that comes with WebSphere Portal; see one of the following links for information.

   - WebSphere Application Server Version 6.1: Preparing Linux systems for installation
   - WebSphere Application Server Version 7.0: Preparing Linux systems for installation

2. Set the file descriptor limit to 10240; for example, `ulimit -n 10240`.

3. **Web Content Management only:** Use the `ulimit -f` command to set the maximum size of files that can be created to be at least the size of the largest file you would need to upload to the content server. The command `ulimit -f unlimited` removes any limit on file size.

4. Install and configure X server on Linux (for example X-Windows or GNOME) to use the graphical user interface the installation program provides. **Note:** X server is not required if installing with a response file or in console mode.

**Parent topic:** Setting up a cluster on Linux  
**Previous topic:** Preparing prerequisite and corequisite software on Linux  
**Next topic:** Preparing the primary node on Linux
Preparing the primary node on Linux

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

**Prerequisites**

- Preparing prerequisite and corequisite software on Linux
- Preparing your Linux operating system

Perform the following tasks to prepare your primary node:

1. **Installing WebSphere Portal on Linux on the primary node**
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. **Configure WebSphere Portal to use a remote database**
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

3. **Configuring the primary node to communicate with the deployment manager on Linux**
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. **Removing search collections on Linux**
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Parent topic:** Setting up a cluster on Linux

**Previous topic:** Preparing your Linux operating system

**Next topic:** Choosing the type of cluster to create on Linux
Installing WebSphere Portal on Linux on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method.

Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.
   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities
4. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:
   - **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   - A. Install the current supported version of WebSphere Application Server as a root user.
   - B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:
     1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
     2. Run the following tasks to change the rights of the non-root user:
        ```bash
        chmod -R g+rwx /opt/IBM
        chgrp -R group_name /opt/IBM
        chmod -R g+wr /tmp
        ```
C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

**Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

**Restriction:** When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \. depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Table 1. Installation task options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Installation type</strong></td>
</tr>
<tr>
<td><strong>Graphical user interface</strong></td>
</tr>
<tr>
<td><strong>Console mode</strong></td>
</tr>
<tr>
<td><strong>Silent install</strong></td>
</tr>
</tbody>
</table>

**Note:** If the installation program does not detect a WebSphere Application Server instance that you know exists, exit the installation program and pass the WebSphere Application Server instance location using the command line; for example, ./install.sh -W was.undetectedWas="/my/WAS/location".

**Note:** If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

6. Verify your installation was successful; access WebSphere Portal using the http://yourserver:yourport/wps/portal format. Run the ./ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the ./ConfigEngine.sh configure-express -DPortalAdminPwd=password -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

**Restriction:** Run the configure-express task before configuring your database, user registry, context root, security, etc. If you ran any tasks other than the install task, do not run this task.

**Note:** See http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html for tutorials on how to use the sample content.

The sample content includes:

- Creates a group called contentAuthors; members of this group are given privileges to create content in the sample
Internet and intranet sites. Navigate to the Administration area and then click Access > Users and Groups.
- Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0".
- Navigate to the Administration area and then click Portal Content > Web Content Libraries.
- Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the Environment area.
- Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to the Theme Customizer and then select the style.
- Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.
- Creates two virtual portals with context roots of wps/portal/intranet and wps/portal/internet. These are the sample Internet and intranet sites. Go to http://yourserver:yourport/wps/portal/internet and http://yourserver:yourport/wps/portal/intranet to access them.
- Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the Administration area and then click Access > Credential Vault > Manage System Vault Slots.
- Modifies the portlet palette to include some new portlets. Click the Portlets link to see the portlet palette.

8. Optional: If you ran the configure-express task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as uid=xyzadmin,o=defaultWIMFileBasedRealm. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:
   A. Edit the wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.
   B. Add the following line to the file:

   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

   Replace portal_admin_DN with the distinguished name of the portal administrator.
   C. Save your changes and close the file.
   D. Run the ./ConfigEngine.sh action-express-memberfixer -DPortalAdminPwd=password -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number task, located in the wp_profile_root/ConfigEngine directory.

9. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:
   Note: The starting port parameter is required for a successful completion of the modify-ports-by-startport task.
   Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.
   A. Stop the server1 and WebSphere_Portal servers.
   B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./[ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number]</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

**Note:** Sample port files are available on the Setup disc.

```
./ConfigEngine.sh modify-ports-by-portsfile -DWasPassword=password -DModifyPortsServer=servername -DPortsFile=full path to ports file
```

The following is an example of the information within a port file although the port values will be different based on your environment:

```
BOOTSTRAP_ADDRESS=10031
SOAP_CONNECTOR_ADDRESS=10033
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=10032
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=10025
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=10036
WC_adminhost=10027
WC_defaulthost=33344
DCS_UNICAST_ADDRESS=10029
WC_adminhost_secure=10039
WC_defaulthost_secure=10035
SIB_ENDPOINT_ADDRESS=10026
SIB_ENDPOINT_SECURE_ADDRESS=10037
SIB_MQ_ENDPOINT_ADDRESS=10030
SIB_MQ_ENDPOINT_SECURE_ADDRESS=10028
ORB_LISTENER_ADDRESS=10034
```

Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

Password considerations when transferring data manually

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts. Alternatively, you can specify the password on the command line using the following syntax:

- Windows: ConfigEngine.bat task_name -Dpassword_property_key=password_value
- UNIX: ./ConfigEngine.sh task_name -Dpassword_property_key=password_value
- i5/OS: ConfigEngine.sh task_name -Dpassword_property_key=password_value

As with other properties, each password property must have the -D prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each -Dproperty=value setting.

- Prerequisites
  - Installing WebSphere Portal on Linux on the primary node
  - Technotes for database connectivity issues

- Configuring WebSphere Portal to use DB2
  View information on installing and setting up DB2 to work with WebSphere Portal.

- Configuring WebSphere Portal to use DB2 for z/OS
  View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle
  View information on installing and setting up Oracle to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle RAC
  View information on installing and setting up Oracle RAC to work with WebSphere Portal.

- Configuring WebSphere Portal to use SQL Server
  View information on installing and setting up SQL Server to work with WebSphere Portal.

- Verifying databases
  After you configure IBM WebSphere Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

Troubleshooting WebSphere Portal Version 6.1 databases
Configuring WebSphere Portal to use DB2

View information on installing and setting up DB2 to work with WebSphere Portal.

1. Installing DB2
   View information on installing DB2 for use with WebSphere Portal.

2. Create users
   View the steps to set up users for DB2 to work with WebSphere Portal.

3. Creating remote databases
   A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

4. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

5. Modifying database properties
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

6. Optional: Configuring JCR collation support
   View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

7. Configure WebSphere Portal to use DB2
   View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

8. Configuring DB2 for large file handling in Web Content Management
   If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the fullyMaterializeLobData property in the WebSphere Application Server administrative console.

9. Optional: Changing driver types
   WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2

View information on installing DB2 for use with WebSphere Portal.

Before you begin:

- Make sure DB2 is set up with updated kernel parameters according to the recommendations in the DB2 Quick Beginnings guide at DB2 Technical Support.
- **(For Type 2 drivers only):** DB2 Connect must be installed on the same system as WebSphere Portal, and have the same name as the server profile name.
- When you install DB2 using the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.

1. If you are using the JDBC driver in type 2 mode, configure your DB2 Connect client with the following commands. If you are using a remote database, complete this step separately from the WebSphere Portal installation.
   - `db2 update dbm cfg using tp_mon_name WAS`
   - `db2 update dbm cfg using spm_name $hostname`, where $hostname is the host name of WebSphere Portal.
   
   Because the default for spm_name is the hostname itself, specifying the hostname parameter is optional. If your hostname is more than eight characters, use empty double quotes (" "). For example, `db2 update dbm cfg using spm_name " "`.

2. Before installing DB2, log in with a user ID that has administrative authority. The system user ID and password must match the database user ID and password for the WebSphere Portal databases. If you do not use the default DB2 database user ID, or if you must access a remote database, create the system user ID before installing DB2.

To set up the environment for the database access:
A. The initialization script for this user (for example, user-home/.profile) must contain a call to the `db2profile` script in the db-home/sqllib directory.
B. After you create the system user ID and password for the DB2 installation, add the user ID to the DB2 administration group (such as `db2adm`) for that system.

   To ensure that the user is set up correctly, login with this user ID and start the DB2 command line processor by executing the command: `db2`. If the command line processor displays, the user ID is set up correctly.

3. To install DB2, follow the instructions that are provided with the DB2 documentation to install DB2 and the required fix pack.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Next topic:** Create users

**Related Information**

- DB2 Information Center
Create users

View the steps to set up users for DB2 to work with WebSphere Portal.

Before you begin: You should have completed Installing DB2.

- **Prerequisites**
  - Installing DB2

For all databases, use one user with administrative rights on the operating system and the DB2 installation. This user can be the database administrative user that is created automatically by the DB2 installation program. This user is the database configuration user that will be used for configuration tasks: creating database tables and performing database transfer. If you choose to have WebSphere Portal also create the databases, the database user should be given SYSADM rights. You only need to manually create an administrator ID when you do not want to use an existing DB2 administrator ID.

A common user name is `db2inst1`, but you can assign any user name as long as it has administrative access and follows the limitations listed here. Do not change the user name after creating it.

The limitations on user names are:
- User names can contain one to eight characters.
- Group and instance names can contain one to eight characters.
- Names cannot be any of the following: `users`, `admins`, `guests`, `public`, `local`
- Names cannot begin with: `IBM`, `SQL`, `SYS`
- Names cannot include accented characters.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Following are the basic steps to create new users and grant privileges. For more information, refer to the DB2 product documentation.

1. From the DB2 Control Center, expand the object tree until you find the DB Users folder.
2. Right-click the DB Users folder and select Create/Add. The Create DB User notebook opens.
3. In the User name field, type a user ID.
4. Assign an authority for the user.
5. Click OK.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Installing DB2

**Next topic:** Creating remote databases
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before creating these databases, note the following information:

- Use IBM® DB2 Universal Database™ Enterprise Server Edition JDBC driver, JCC, type 4.
- If the DB2 JDBC type 4 driver is used, only the instructions on the remote server are required. You do not need to install the DB2 client software, and you do not need to complete the steps related to the DB2 client.
- The client software, DB2 Connect, must be correctly configured to connect to the remote DB2 server instance, for example, db2inst1.
- These instructions assume that a remote DB2 server and DB2 Connect are already installed and running. For information on installing DB2 Connect, see the DB2 product documentation.

**Prerequisites**

- Installing DB2
- Create users

To create a database, you must be a DB2 System Administrator with sufficient database privileges (SYSADM or at a minimum SYSCTRL).

1. Log in to the DB2 server system as a user with sufficient database privileges.
2. Initialize a DB2 command environment by opening a command prompt and typing `su - db2inst1`, where `db2inst1` is the database user. The prompt changes to your operating system shell prompt, for example: `$`. In this mode, you must type `db2` at the beginning of each command and use double quotation marks (``) around the entire command. The following example shows how to use the double quotes; it is not an actual command that you run:

   ```
   db2 "CREATE REGULAR TABLESPACE SMS PAGESIZE 4 K MANAGED BY SYSTEM USING ('sms') BUFFERPOOL SMSPOOL"
   ```

   **Note:** If you are using the Command Line Processor (CLP), refer to your DB2 documentation for details. The command prompt is `db2=>`. In this mode, commands can be entered without the `db2` prefix or the double quotation marks. However, the following steps assume you are not using the CLP and are entering commands from your operating system shell prompt, for example: `$`.

3. Run the following commands on the DB2 server system to configure the DB2 database instance:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>db2set DB2_RR_TO_RS=YES</code></td>
</tr>
<tr>
<td></td>
<td><code>db2set DB2_EVALUNCOMMITTED=YES</code></td>
</tr>
<tr>
<td></td>
<td><code>db2set DB2_INLIST_TO_NLJN=YES</code></td>
</tr>
<tr>
<td></td>
<td><code>db2 &quot;UPDATE DBM CFG USING query_heap_sz 32768&quot;</code></td>
</tr>
<tr>
<td></td>
<td><code>db2 &quot;UPDATE DBM CFG USING maxagents 500&quot;</code></td>
</tr>
<tr>
<td></td>
<td><code>db2 &quot;UPDATE DBM CFG USING sheapthsres 0&quot;</code></td>
</tr>
</tbody>
</table>

4. **(Important)** Failure to complete this step will result in an unsuccessful database transfer. Run the following commands on the DB2 server system to create the necessary databases:

   **Notes:**
   - Replace `dbname` with the actual name of the database. Run the commands and each time replace `dbname` with the actual values for release, community, customization, Java Content Repository, Feedback, and Likeminds. You will need to run the commands once for each database for a total of six times.
   - **Remember:** DB2 database names cannot
exceed eight characters. Therefore, consider using these database names: release, commun, custom, jcrdb, fdbkdb, and lmdb.

```
db2 "CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192"
db2 "UPDATE DB CFG FOR dbname USING applheapsz 4096"
db2 "UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024"
db2 "UPDATE DB CFG FOR dbname USING stmtheap 32768"
db2 "UPDATE DB CFG FOR dbname USING dbheap 2400"
db2 "UPDATE DB CFG FOR dbname USING locklist 1000"
db2 "UPDATE DB CFG FOR dbname USING logfilsiz 4000"
db2 "UPDATE DB CFG FOR dbname USING logprimary 12"
db2 "UPDATE DB CFG FOR dbname USING logsecond 20"
db2 "UPDATE DB CFG FOR dbname USING logbufsz 32"
db2 "UPDATE DB CFG FOR dbname USING avg_appls 5"
db2 "UPDATE DB CFG FOR dbname using AUTO_MAINT off"

Complete the following:

A. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (jcrdb).

  - `jcrdb` is the name of the database used to store user data and objects
  - `jcr` is the jcr user for `jcrdb`
  - `dbpassword` is the password for the jcr user for the `jcrdb`

```
db2 "CONNECT TO jcrdb USER jcr USING dbpassword"
db2 "CREATE BUFFERPOOL ICMLSFRQBP4 SIZE 1000 PAGESIZE 4 K"
db2 "CREATE BUFFERPOOL ICMLSVOLATILEBP4 SIZE 16000 PAGESIZE 4 K"
db2 "CREATE BUFFERPOOL ICMLSMAINBP32 SIZE 16000 PAGESIZE 32 K"
db2 "CREATE BUFFERPOOL ICMLSFREQBP4 SIZE 1000 PAGESIZE 4 K"
db2 "CREATE REGULAR TABLESPACE ICMLFQ32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLFQ32') BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMLNF32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLNF32') BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMVFPQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMVFPQ04') BUFFERPOOL ICMLSVOLATILEBP4"
db2 "CREATE REGULAR TABLESPACE ICMSFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMSFQ04') BUFFERPOOL ICMLSFREQBP4"
db2 "CREATE REGULAR TABLESPACE CMBINV04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('CMBINV04') BUFFERPOOL CMBMAIN4"
db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSYSSTSPACE32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('icmlsysstspace32') BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE SYSTEM TEMPORARY TABLESPACE ICMLSYSSTSPACE4 PAGESIZE 4 K MANAGED BY SYSTEM USING ('icmlsysstspace4') BUFFERPOOL ICMLSVOLATILEBP4"

```
db2 "DISCONNECT jcrdb"
db2 "TERMINATE"
```

B. For JDBC Type 2 connections only: On DB2 Connect, use a text editor to open the /etc/services file. If it does not specify the DB2 connection service port, add the following text to specify the port for the remote DB2 instance:

```
db2 -inst1port1/tcp # DB2 connection service port
```

where `db2inst1` is the name of the DB2 instance ID on the system, and `port1` with the actual port number that is
assigned to the DB2 connection service in your DB2 server installation. The connection service port on the DB2 Client system, WebSphere Portal server, must match the connection service port on the DB2 server. The ports should match by number but not necessarily by name.

C. Set up the correct service name by entering the following command on the DB2 server system:  
   `db2 "UPDATE DBM CFG USING svcename svce_name"` where `svce_name` is the connection service port name that is specified above.

D. For JDBC Type 2 connections only: On DB2 Connect, set DB2COMM to TCP/IP by using the `db2set` command:
   `db2set DB2COMM=tcpip`.

E. For JDBC Type 2 connections only: Catalog the TCP/IP node with the IP address of the remote database server on DB2 Connect:
   `db2 "catalog tcpip node remote_db_node_alias remote database_server_node server connection_service_port"` where:
   - `remote_db_node_alias` is the alias name of the database server that you are defining for the WebSphere Application Server node name. The alias name can contain one to eight characters.
   - `database_server_node` is the fully qualified host name of your database server system.
   - `connection_service_port` is the name of the DB2 connection service port that is configured in the `/etc/services` file on the database server system.

F. For JDBC Type 2 connections only, catalog the WebSphere Portal databases on DB2 Connect, where:
   - `remote_db_name_domain` is the cataloged name of the databases on the server system for each domain.
   - `domain_alias_name` is the database alias names that you are defining.
   - `remote_db_node_alias` is the name that was used previously when you cataloged the TCP/IP node in the previous step.

   The alias for each database must be different from the actual database name and can only contain up to eight characters:
   `db2 "catalog db remote_db_name_domain as domain_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_release as release_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_community as comm_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_customization as cust_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_fdbkdb as fdbkdb_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_lmdb as lmdb_alias_name at node remote_db_node_alias"`
   `db2 "catalog db remote_db_name_jcrdb as jcrdb_alias_name at node remote_db_node_alias"`

G. For JDBC Type 2 connections only: Log out of DB2 Connect by entering `db2 "terminate"`.

H. For JDBC Type 2 connections only, on DB2 Connect, test your remote connection by issuing the following command in the DB2 command window:  
   `db2 "connect to alias_name user username using password"`, where `alias_name` is the alias name that you defined above, `username` is the database user, and `password` is the password assigned to the database user.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Create users  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword IN and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - **Windows:** `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - **UNIX:** `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Creating remote databases  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release.DbName = release
  - jcr.DbName = jcrdb
  - feedback.DbName = fdbkdb
  - likeminds.DbName = lmdb
  - community.DbName = commdb
  - customization.DbName = custdb

  - If you are using a remote database, enter the values for the remote server.
  - Use a forward slash (/) instead of a backslash (\).
  - There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
  - The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.

  - Depending on which database domain has to be configured, replace dbdomain with:
    - release
    - customization
    - community
    - jcr
    - feedback
    - likeminds

  - The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   A. For `dbdomain.DbType`, type `db2`.
   B. For `dbdomain.DbName`, type the name of the WebSphere Portal domain database. **Notes:**
      - This value is also the database element in the `dbdomain.DbUrl` property.
      - This value is the TCP-IP alias for the database.
   C. For `dbdomain.DbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For `dbdomain.DataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For `dbdomain.DbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of `DbName`.
   F. For `dbdomain.DbUser`, type the user ID for the database administrator.
   G. For `dbdomain.DbPassword`, type the password for the database administrator.
   H. Optional: For `dbdomain.DbRuntimeUser`, type the user ID of the database user that should be used by WebSphere Portal to connect to the database at runtime.
   I. If `dbdomain.DbRuntimeUser` is specified, you must set `dbdomain.DbRuntimePassword` to be the password of the runtime database user.
   J. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.
K. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

L. For `dbdomain.XDbName`, type the database loop back alias that needs to be set if you plan to use the `create-database` task. **Note:** Required only for local databases using a JDBC Type 2 driver.

M. For `dbdomain.DbNode`, type the value for the node database. Set this value if you want to call `create-database`. **Note:** Required only for local databases.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

B. For `source.domainDbName`, type the name of the database domain you are currently using.

C. For `source.domainDbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domainDbUrl`, type the url currently used to access your database.

F. For `source.domainDbUser`, type the name of the user accessing this database.

G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `db2.DbDriver`, type the name of the JDBC driver class.

   B. For `db2.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `db2.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.
Configuring JCR collation support

View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

1. Stop the WebSphere Portal server:
   ```bash
   ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```
2. If using a remote DB2 server, copy the following files from the WebSphere Portal server to a temporary directory on the remote DB2 server:
   ```bash
   PortalServer_root/jcr/prereq.jcr/config/collation.jar
   PortalServer_root/jcr/prereq.jcr/config/registerCollationUDFTemplate.sql
   ```
3. Set up collation on the database where the JCR domain is located.
   A. Change to the directory `db2_instance_owner_home/sqllib/function`.
   B. Execute the command:
      ```bash
      Remote DB2:
db2_instance_owner_home/sqllib/java/jdk/bin/jar -xvf temporary location/collation.jar icm/CollationUDF.class
      ```
      ```bash
      Local DB2:
db2_instance_owner_home/sqllib/java/jdk/bin/jar -xvf PortalServer_root/jcr/prereq.jcr/config/collation.jar icm/CollationUDF.class
      ```
   C. If using a local DB2, change to the directory `wp_profile_root/PortalServer/jcr/config`. If using a remote DB2, change to the temporary directory where you copied the files in a previous step.
   D. Open the file `registerCollationUDFTemplate.sql` and change all `SCHEMA` references to the JCR schema; for example, `JCR`. The value set for `SCHEMA` should match the value set for the `jcr.DbSchema` property. You specify `jcr.DbSchema` in the configuration file `wkplc_comp.properties` when you modify database properties.
   E. Connect to the JCR database by running `db2 connect to <jcrdb> user <userid> using <password>`. You must connect to the JCR database using the userid and password of the WebSphere Portal JCR data source.
   F. Execute the following command in the previous substep. If the command completes successfully, the UDF is registered correctly as follows:
      ```bash
      values schema.sortkeyj('abc','en'),
      ```
      where `schema` is the schema used in the previous substep.
   G. Disconnect from the JCR database.
   H. Restart the DB2 instance.
4. Verify that the UDF is registered properly.
   A. Log in as the `db2instanceID`. Open a DB2 terminal window, and type `db2`. From the command line, type the command `connect to JCRDB user userid using password`. You must connect to the JCR database using the userid and password of the WebSphere Portal JCR data source.
   B. Execute the following command in the previous substep. If the command completes successfully, the UDF is registered correctly as follows:
      ```bash
      values schema.sortkeyj('abc','en'),
      ```
      where `schema` is the schema used in the previous substep.
   C. Edit the `icm.properties` file, located in `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory. Add the following section to the end of the file:
      ```bash
      # Enable/Disable collation support for all DB2 platforms
      ```

1622
# Disabled by default
jcr.query.collation.db2.enabled = true

# Database specific collation mappings
# These mappings apply map a Java locale name into a collation name
# supported by the underlying database.
# Example mappings for DB2 platform

# English
jcr.query.collation.en = en

# Swedish
jcr.query.collation.sv = sv

jcr.query.collation.zh = zh
jcr.query.collation.de = de
jcr.query.collation.da = da
jcr.query.collation.hu = hu
jcr.query.collation.jp = jp

6. Enter the following command to start the WebSphere Portal server:../startServer.sh WebSphere_Portal
Configure WebSphere Portal to use DB2

View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

**Prerequisites**

- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties

**Tips:**

- To run these tasks as a non-root user, you must first run the task chown -R non-root_userWebSphereDir.
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

**Steps for transferring data to another supported database**

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.
   A. Locate the file /home/db2inst1/sqllib/cfg/db2cli.ini.
   B. Add the following to the end of the file. Leave an empty line after ReturnAliases=0.[COMMON]

   ```
   [COMMON]
   DYNAMIC=1
   ReturnAliases=0
   ```

2. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.

3. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2.

   ```
   /home/db2inst1/sqllib/db2profile
   ```

   where db2inst1 represents your database instance**Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

4. Enter the following commands to validate configuration properties...

   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```

5. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
6. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

7. Transfer the database:

   **Important:** Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.
   B. Enter the following command: `./ConfigEngine.sh database-transfer -DWasPassword=password`

      **Note:**
      - To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: `./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password`
      - If you have been storing data in IBM® Derby for a long time, database transfer could fail with OutOfMemory exceptions. If database transfer fails, add the following property to the command in this step: `./ConfigEngine.sh database-transfer -DDbtJavaMaxMemory=1536M -DWasPassword=password`

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

8. After transferring the database tables, perform a `reorg` check to improve performance. Perform this step for each database alias in the property file.

   A. Connect to a database with the following command: `db2 connect to database_alias user db2admin_userid using password`

      **Note:** Additional options might be required if additional security has been installed. Refer to DB2 Universal Database commands by example for links to the command reference.

   B. After it is connected, run the following commands from the DB2 prompt: `db2 reorgchk update statistics on table all > xyz.out`

   C. Look in the `reorg` column for entries marked with a * (star or asterisk) in the file `xyz.out`. For each line with a *, note the `tablename` and run the following command for each `tablename`: `db2 reorg table tablename db2 terminate db2rbind database_name -l db2rbind.out -u db2_admin -p password`

   D. The output file `db2rbind.out` is only created when there is an error for the `db2rbind` command.

9. Change to the directory `wp_profile_root/bin`.

10. Enter the following command to start the WebSphere Portal server: `./startServer.sh WebSphere_Portal`
Configuring DB2 for large file handling in Web Content Management

If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the fullyMaterializeLobData property in the WebSphere Application Server administrative console.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configure WebSphere Portal to use DB2

**Note:** You only need to perform these steps if you are using Web Content Management.

1. Log into the WebSphere Application Server administrative console.
2. Click **Resources > JDBC > Data sources**.
3. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
4. Select the name of the data source that is defined in wkplc_comp.properties for the JCR database domain. The default data source is **wpdbDS**.
5. Click **Custom properties**.
6. Ensure that the fullyMaterializeLobData property is set to false.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Configure WebSphere Portal to use DB2  
**Next topic:** Changing driver types
Changing driver types

WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Before you begin, ensure that the following conditions are met:

- The WebSphere Portal database has been successfully transferred to DB2 using the database-transfer configuration task.
- The files wkplc_comp.properties and wkplc_dbtype.properties have been modified to set the correct values for the DB2 drivers that you are switching to:

  In the file wkplc_comp.properties set each <Domain>.DbUrl property using the following formats:
  
  # db2 (type 2):        { jdbc:db2:wpsdb }
  # db2 (type 4):        { jdbc:db2://<YourDatabaseServer>:50000/wpsdb:returnAlias=0; }

  In the file wkplc_dbtype.properties set the db2.DbLibrary property using the following format:

  # For DB2 Type 2
driver use <SQLLIB>/java/db2java.zip
  # For DB2 Type 4 driver use <SQLLIB>/java/db2jcc.jar:<SQLLIB>/java/db2jcc_license_cu.jar

  In the file wkplc_dbtype.properties set the db2.DbDriver property using the following format:

  # For DB2 Type 2
driver use com.ibm.db2.jcc.DB2Driver
  # For DB2 Type 4 driver use com.ibm.db2.jdbc.app.DB2Driver

**Note:** If WebSphere Portal is installed on the same machine as the DB2 server and you switch from a JDBC Type 4 connection to a JDBC Type 2 connection, verify that you have created the alias names for the DB2 databases as described in Creating remote databases and that the alias names are specified for the databases in the file wkplc_comp.properties. When switching from a JDBC Type 2 connection to a JDBC Type 4 connection, remove the database alias names and refer to the databases directly. This is required because of a limitation in the DB2 Universal JDBC driver.

**Prerequisites**

- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties
- Configure WebSphere Portal to use DB2
- Configuring DB2 for large file handling in Web Content Management

1. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.
2. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2.

   ```bash
   /home/db2inst1/sqllib/db2profile
   
   where db2inst1 represents your database instance
   **Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

3. Enter the following commands to validate configuration properties.

   ```bash
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```

Operating systems: AIX, HP-UX, i5/OS, Linux, Solaris, Windows
4. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

```
Option                     Description
WebSphere Application Server  ./stopServer.sh server1 -username admin_userid -password admin_password
WebSphere Portal             ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
```

6. Change to the directory `wp_profile_root/ConfigEngine`.

7. To change from one supported driver to the other, run the following task to connect the database, including only the domains that require the switch:

```
```

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

1. Installing DB2 for z/OS
   View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

2. Creating users
   Complete this procedure to set up users for IBM DB2 Universal Database™ for z/OS® to work with IBM WebSphere Portal.

3. Creating remote databases
   A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

4. Optional: Creating the Java Content Repository database
   View information on setting up your Java Content Repository database to work with WebSphere Portal.

5. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

6. Configuring WebSphere Portal to use DB2 for z/OS
   View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2 for z/OS

View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

The following prerequisites must exist separately from the WebSphere Portal installation:

- If you are using the DB2 Legacy Type 2 JDBC driver, configure your DB2 Connect client with the following commands:
  - `db2 update dbm cfg using tp_mon_name WAS`
  - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name for the machine where the DB2 Connect client is installed (same as portal machine).

- If you are using the DB2 Legacy Type 2 JDBC driver, enable extended shared memory usage with the following commands:
  - `export EXTSHM=ON`
  - `db2set DB2ENVLIST=EXTSHM`
  - `db2start`

  To make the change permanent, you must add the environment variable by adding the following to the `profile.env` file:

  ```
  DB2ENVLIST='EXTSHM'
  ```

  in `/home/db2inst/sqllib/userprofile`

  add: `export EXTSHM=ON`

  **Note:** The shell must be reopened before restarting DB2 for z/OS.

- Both type 2 and type 4 drivers are supported. If you are using the DB2 Legacy Type 2 JDBC driver, the DB2 Connect client must be installed on the same machine as WebSphere Portal to connect to the remote database.

- The DB2 subsystem must be on a supported z/OS platform.

- Update the BP8K0 catalog bufferpool to 35,000 buffers before performing database transfer. You should change this value based on your environment. The SYSIBM.SYSDATABASE table resides in this bufferpool and is used extensively by DB2 for z/OS during database transfer.

To use DB2 for z/OS as the database software for WebSphere Portal, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions. Refer to the Planning for DB2 for z/OS topic for additional considerations for configuring DB2 for z/OS as the WebSphere Portal database.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Next topic:** Creating users
Creating users

Complete this procedure to set up users for IBM® DB2 Universal Database™ for z/OS® to work with IBM WebSphere® Portal.

Before you begin: You should have completed Installing DB2 for z/OS.

- **Prerequisites**
  - Installing DB2 for z/OS

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

- If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, you must create a unique database user for each WebSphere Portal instance. By default all database table names include the name of the database user used to access the data. Therefore, to prevent table name conflicts, you must create a unique database user for each WebSphere Portal instance on the shared DB2 for z/OS subsystem.

- Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Use the following steps to grant access permissions to the database users. Repeat these steps for each WebSphere Portal instance you are setting up.

1. Create all database user IDs in the security product you are using on z/OS. For jcrschema, the database schema name for IBM Java Content Repository data, create a group and connect it to the database user ID for Java Content Repository data, jcr. The following sample shows the RACF definition of such a user ID and group, where jcr is the database user ID for Java Content Repository data, yourDefaultUserGroup is your default RACF group for database user IDs, jcrschema is the database schema name for Java Content Repository data, and yourDefaultGroup is your default RACF group for groups. If you have some other security product such as Top Secret or ACF2 instead of RACF, translate the sample RACF definition into the appropriate syntax before running the job.

   ```
   ADDUSER jcr DFLTGRP(yourDefaultUserGroup) NAME('WAS DB2 ACCESS USER')
   PW USER(jcr) NOINTERVAL
   ALU jcr PASSWORD(********) NOEXPIRED
   ADDGROUP jcrschema SUPGROUP(yourDefaultGroup)
   CONNECT jcr GROUP(jcrschema)
   ```

2. Run the following SQL statements using a tool like SPUFI while logged on to the DB2 subsystem to grant appropriate rights on the newly created databases. If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, be sure to use the database user associated with the WebSphere Portal instance you are setting up. **Note:** Make sure your vmmdb user follows these same standards.

where:
3. releasenameonzos, communitynameonzos, customizationnameonzos, and releaseusr, communityusr, customizationusr represent the databases and database users, respectively, of the WebSphere Portal instance you are setting up. (These users must be created on the host system.)

- jcrdbnameonzos and jcr are the database and database user, respectively, for Content Repository data.
- fbdbdbnameonzos and feedback are the database and database user, respectively, for Feedback data.
- lmdbnameonzos and lmdbusr are the database and database user, respectively, for Likeminds data.

- jcrschema is the database schema name for Content Repository data.

3. Grant the necessary access rights to all users who might require them. Depending on the architecture that you choose, these users might include Java Content Repository and Feedback users.

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Installing DB2 for z/OS
Next topic: Creating remote databases
Creating remote databases

A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

Before you begin, complete the following prerequisites:

- These instructions assume that you will use a local IBM® DB2 Universal Database™ Enterprise Server Edition Connect to connect to a remote IBM DB2 Universal Database for z/OS® server, and that IBM WebSphere® Application Server, WebSphere Portal, and DB2 Connect will be installed on the same machine.

- To run SQL statements, you can use a tool like SPUFI. The specified statements include CREATE STOGROUP, CREATE DATABASE and CREATE TABLESPACE. For CREATE STOGROUP you have to replace the icmvolumes and icmvcat variables with volume serial numbers and a catalog name for your environment. For CREATE TABLESPACE you can specify a specific BUFFEROOL. Refer to the DB2 for z/OS SQL Reference for a description of these options.

- Ensure that a TEMP database is created for your subsystem. You can use the following statements to create a TEMP database:

```
CREATE DATABASE db_name AS TEMP;
CREATE TABLESPACE ts_name IN db_name;
```

- Log on to the DB2 subsystem on the host server. DB2 system administrator rights are needed to create the databases.

- Replace variables as follows:

  - releasenameonzos, communitynameonzos, and customizationnameonzos are the WebSphere Portal databases for WebSphere Portal and Member Manager data.
  - fdbkdbnameonzos and fdbkdbts are the database and table space, respectively, for Feedback data.
  - lmdbnameonzos and lmdbts are the database and table space, respectively, for LikeMinds data.

- Because large objects are stored in columns that can become very large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for tablespaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see Technote 1306637, Managing LOB logging in DB2 for z/OS.

- Prerequisites

  - Installing DB2 for z/OS
  - Creating users

Use the following steps to set up WebSphere Portal with a remote instance of DB2 for z/OS. Refer to Planning for DB2 for z/OS for a list of databases and table space names. If you are configuring multiple WebSphere Portal instances to use a single DB2 subsystem, be sure to use the database and table space names associated with the WebSphere Portal instance you are setting up.

1. CREATE DATABASE releasenameonzos CCSID UNICODE;
2. CREATE DATABASE communitynameonzos CCSID UNICODE;
3. CREATE DATABASE customizationnameonzos CCSID UNICODE;
4. Execute the steps in the topic Creating the Java Content Repository database.
5. CREATE DATABASE fdbkdbnameonzos CCSID UNICODE;
6. CREATE TABLESPACE fdbkdbts IN fdbkdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500 LOCKSIZE ROW;
7. CREATE DATABASE lmdbnameonzos CCSID UNICODE;
8. CREATE TABLESPACE `lmdbts` IN `lmdbnameonzos` USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500;

Related Information

- Managing LOB logging in DB2 for z/OS
Creating the Java Content Repository database

View information on setting up your Java Content Repository database to work with WebSphere Portal.

First, you need to create multiple databases for scalability.

The IBM Java Content Repository database grows in size as the IBM® WebSphere® Portal server is used. To support this growth, which includes the dynamic creation of many new tables within the database, the WebSphere Portal server allows you to create multiple databases within a single IBM DB2 Universal Database™ for z/OS® subsystem. A minimum of two databases is recommended, but more can be created if necessary. A single database setup is not recommended; it will quickly become constrained. See the Performance guides on the product documentation Web site for more information.

Each database that is created must begin with a common prefix; there is no convention required for the remainder of the name. For example, to create \textit{xx} number of databases, you may choose to use the following commands:

\begin{verbatim}
CREATE DATABASE JCRDB01
CREATE DATABASE JCRDB02
... 
CREATE DATABASE JCRDBxx
\end{verbatim}

In this case, \textit{JCR} is the common prefix. You also have to select a maximum number of user-defined tables (UDT) that each database will be allowed to hold; the recommended value is 400.

\textbf{- Prerequisites}

- Installing DB2 for z/OS
- Creating users
- Creating remote databases

A sample script of the commands that you can use to create the Java Content Repository database in your DB2 for z/OS installation is shown below. The sample demonstrates the creation of a single database. To follow the recommendation of creating at least two databases, duplicate the commands for each additional database as indicated below. Find a template of these commands in the file \texttt{PortalServer\_root/installer/wp.config/config/templates/db/db2\_zos/jcr\_sample.sql}.

\textbf{Notes:}

- It is not necessary to duplicate every tablespace definition in every database.
- In order to run the commands shown in the sample, you must know the database name and the IDs of the MVS volumes where the Java Content Repository database tables will be stored.
- Edit the template file for your installation environment before running the commands shown in the sample:
  - Replace \texttt{jcrdbnameX} with the name of the database. Remember that each database name must begin with a common prefix.
  - Replace \texttt{stogroup} with the name of your storage group.
  - Replace \texttt{icmvolumes} with the IDs of the MVS volumes where the Java Content Repository database tables will be stored. These values are assigned by the database administrator.
  - Replace \texttt{icmvcat} with the name of the virtual catalog.
  - Replace \texttt{jcr} with the name of database user ID.
  - Replace \texttt{4kbp} with the name of your 4K bufferpool.
  - Replace \texttt{32kbp} with the name of your 32K bufferpool.
  - Replace \texttt{jcrschema} with the schema name of your Java Content Repository domain.
CREATE STOGROUP stogroup VOLUMES (icmvolumes) VCAT icmvcat
GRANT USE OF STOGROUP stogroup to jcr

CREATE DATABASE jcrdbnameX STOGROUP stogroup BUFFERPOOL 4kbp INDEXBP 4kbp CCSID UNICODE

Note: The following two tablespace commands must be created in every database:
CREATE TABLESPACE ICMLFQ32 IN jcrdbnameX USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 4kbp CCSID UNICODE

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Creating remote databases
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the \wp_profile_root\PortalServer\config\tablespaces\dbdomain.space_mapping.properties file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing DB2 for z/OS
- Creating users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file \wp_profile_root\PortalServer\config\tablespaces\dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword IN and a space. For example: community.COMP_INST.tablespace=IN COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
   - UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- `i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
Configuring WebSphere Portal to use DB2 for z/OS

View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the `db2cli.ini` file. Failure to follow these steps will cause the database transfer to hang at the task `action-process-constraints`.
   A. Locate the file `/home/db2inst1/sqllib/cfg/db2cli.ini`.
   B. Add the following to the end of the file. Leave an empty line after `ReturnAliases=0`.

   ```
   [COMMON]
   DYNAMIC=1
   ReturnAliases=0
   ```

2. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.

3. Enter the following commands to validate configuration properties...

   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```

4. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

6. Transfer the database: **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.
   B. Enter the following command: `./ConfigEngine.sh database-transfer -DWasPassword=password`

   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter...
the following command: 

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files and then repeat this step.

7. From the command line processor, reset the check pending status on the WebSphere Portal table spaces listed here. CHECK DATA is a DB2 batch utility that is invoked through JCL or through the DB2 utility panels. Type the following utility commands to check pending status:

```
check data tablespace releasenameonzos.TS320A
check data tablespace releasenameonzos.TS280A
check data tablespace releasenameonzos.TS300A
check data tablespace releasenameonzos.TS2110A
check data tablespace releasenameonzos.TS830A
check data tablespace communitynameonzos.TS8000B
check data tablespace communitynameonzos.TS8011B
check data tablespace communitynameonzos.TS280B
check data tablespace customizationnameonzos.TS2110C
check data tablespace jcrdbnameonzos.ICMSFQ04
check data tablespace jcrdbnameonzos.TS2110D
```

where releasenameonzos, communitynameonzos, and customizationnameonzos are the names of your WebSphere Portal databases, and jcrdbnameonzos is the name of your JCR database. Refer to the Utility Guide and Reference for DB2 for z/OS for additional details.

8. Run the RUNSTATS utility as shown in the following example:

```
LISTDEF JCRDBZOS INCLUDE TABLESPACE JCRDBZOS.* BASE
RUNSTATS TABLESPACE LIST JCRDBZOS INDEX(ALL) KEYCARD TABLE(ALL)
LISTDEF JCRDB01 INCLUDE TABLESPACE JCRDB01.* BASE
RUNSTATS TABLESPACE LIST JCRDB01 INDEX(ALL) KEYCARD TABLE(ALL)
...```

9. Start the WebSphere Application Server.

10. Verify that the WebSphere Portal application server is running by opening the following URL in a browser:

```
http://hostname.companyname.com:port_number/wps/portal
```

where hostname.companyname.com is the fully qualified host name of the machine where WebSphere Portal is running and port_number is the transport port that is created by WebSphere Application Server.

If you have performed database transfer in a clustered environment, you must explicitly copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node on which the database-transfer task was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values specified in the icm.properties file.

1. Stop the portal server on the secondary node.
2. Copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node and replace the icm.properties file on the secondary node with the new file from the primary node.
3. Start the portal server on the secondary node.
Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

1. Installing Oracle
   View information on how to install Oracle for use with WebSphere Portal.

2. Creating users
   View the steps to set up users for Oracle to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle databases to work with WebSphere Portal.

4. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configure WebSphere Portal to use Oracle
   This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle

View information on how to install Oracle for use with WebSphere Portal.

You can use Oracle as the database software. You must install Oracle separately and before performing a database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle

Next topic: Creating users
Creating users

View the steps to set up users for Oracle to work with WebSphere Portal.

Before you begin:

- You should have installed Oracle.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for
  WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**

- Installing Oracle

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work
with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example,
avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Start the Oracle SQL command line processor 'SQL*Plus' by entering `sqlplus /nolog` on the operating system
   command prompt

2. Log in to the Oracle database by executing command `connect user/password@database name`. For example:
   `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

3. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, or
   customization.

   A. Log in to the database in which you want to create the new users.

   B. Create the users that you need in the appropriate databases by entering the following commands in the SQL*Plus
      tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user
      objects and `temp_tablespace` is identified to store temporary objects. All names must be in lower case.

      ```
      SQL> create user releaseusr identified by password
      default tablespace user_tablespace
      temporary tablespace temp_tablespace;
      GRANT UNLIMITED TABLESPACE TO releaseusr;
      SQL> create user communityusr identified by password
      default tablespace user_tablespace temporary tablespace temp_tablespace;
      GRANT UNLIMITED TABLESPACE TO communityusr;
      SQL> create user customizationusr identified by password
      default tablespace user_tablespace temporary tablespace temp_tablespace;
      GRANT UNLIMITED TABLESPACE TO customizationusr;
      SQL> create user jcr identified by password
      default tablespace user_tablespace temporary tablespace temp_tablespace;
      GRANT UNLIMITED TABLESPACE TO jcr
      ```

4. Connect to the Feedback database:

   A. Enter the following command: `SQL> connect`
B. Enter user-name:  username/password@dbname where username is an existing administrative user in the database. For example, system/manager@fdbkdb will log the administrative user system with a password of manager into the fdbkdb database.

C. Create the Feedback user:SQL> create user feedback identified by password
default tablespace user_tablespace
temporary tablespace temp_tablespace;

GRANT UNLIMITED TABLESPACE TO feedback

D. Log out of the command line tool using the command SQL> exit.

5. Connect to the LikeMinds database:
   A. Enter the following command:SQL> connect
   B. Enter user-name:  username/password@dbname, where username is an existing administrative user in the database.
      For example, system/manager@lmdb will log the administrative user system with a password of manager into the lmdb database.

C. Create the LikeMinds user:SQL> create user lmdbusr identified by password
default tablespace user_tablespace
temporary tablespace temp_tablespace;

GRANT UNLIMITED TABLESPACE TO lmdbusr

D. Log out of the command line tool using the command SQL> exit.

6. Perform the following steps to verify that you can connect to the database with the user ID and password that you just created:
   A. Enter the SQL> connect command to connect to the content database.
   B. Enter user-name:username/password@dbname, where username is an existing administrative user in the database. For example, system/manager@jcrdb will log the administrative user system with a password of manager into the Oracle database.

Parent topic: Configuring WebSphere Portal to use Oracle
Previous topic: Installing Oracle
Next topic: Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal.

For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:

  - db_block_size = 8192 bytes
  - db_cache_size = 307,200 bytes
  - db_files = 1024 files
  - log_buffer = 65536 bytes
  - open_cursors = 1500 cursors
  - pga_aggregate_target = 204,800 bytes
  - pre_page_sga = true
  - processes = 300 processes
  - shared_pool_size = 204,800 bytes

  **Note:** If you are using IBM Java Content Repository, the open_cursors value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the parallel_max_servers to 1200.
- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:
  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.
  - **EXACT**
When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

- **Prerequisites**
  - Installing Oracle
  - Creating users

Parent topic: Configuring WebSphere Portal to use Oracle
Previous topic: Creating users
Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as **release.DbName**, **jcr.DbName**, **feedback.DbName**, and **likeminds.DbName**. For example:
  - `release(DbName)=release`
  - `jcr(DbName)=jcrdb`
  - `feedback(DbName)=fdbkdb`
  - `likeminds(DbName)=lmdb`
  - `community(DbName)=commdb`
  - `customization(DbName)=custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.

- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomain DbType, type oracle.
   B. For dbdomain DbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomain DbUrl property.
   C. For dbdomain DbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomain.DbName should be the same value used for the dbdomain.DbSchema
      Restriction: The value for dbdomain.DbSchema must equal the value for dbdomain.DbUser.
   D. For dbdomain DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomain DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note:
      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
F. For \textit{dbdomain}.DbUser, type the user ID for the database administrator. **Restriction:** The value for \textit{dbdomain}.DbUser must equal the value for \textit{dbdomain}.DbSchema.

G. For \textit{dbdomain}.DbPassword, type the password for the database administrator.

H. For \textit{dbdomain}.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.

I. For \textit{dbdomain}.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.

J. For \textit{dbdomain}.DbHome, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

   A. For \textit{source.domain}.DbType, type of the database you are currently configured to use. The value for \textit{source.domain}.DbType is Derby by default.

   B. For \textit{source.domain}.DbName, type the name of the database domain you are currently using.

   C. For \textit{source.domain}.DbSchema, type current schema identifier for objects within the database for this domain.

   D. For \textit{source.domain}.DataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

   E. For \textit{source.domain}.DbUrl, type the url currently used to access your database.

   F. For \textit{source.domain}.DbUser, type the name of the user accessing this database.

   G. For \textit{source.domain}.DbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file \textit{wkplc_dbtype.properties}.

   A. For oracle.DbDriver, type the name of the class that SqlProcessor uses to import SQL files.

   B. For oracle.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For oracle.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file \textit{wkplc.properties}.

   A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Creating databases

**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`

3. To create the database users, type the following command:

   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   ```sql
   '<WP_root>/base/wp.db.impl/config/templates/setupdb/sqlserver2005\<database domain>\createUsers.sql'.
   ```

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**

Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `$jcrdb` is the name of the database you created to store user data.
   - `$dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.
   
   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '$dbpath./jcrdb./data/ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '$dbpath./jcrdb./data/ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '$dbpath./jcrdb./data/ICMVFP04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '$dbpath./jcrdb./data/ICMSFP04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '$dbpath./jcrdb./index/ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   
   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

Parent topic: Configuring WebSphere Portal to use Oracle

Previous topic: Setting up databases

Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablesspaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**- Prerequisites**

- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablesspaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`

   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configure WebSphere Portal to use Oracle
Configure WebSphere Portal to use Oracle

This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

**Tips:**
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties:

   `./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password`

   `./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password`

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>
5. Transfer the database. **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.
   
   B. Enter the following command:
   
   ```bash
   ./ConfigEngine.sh database-transfer -DWasPassword=password
   ```
   
   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   ```bash
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```
   
   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:
   ```sql
   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
   ```

7. Change to the directory `wp_profile_root/bin`.

8. Enter the following command to start the WebSphere Portal server:
   ```bash
   ./startServer.sh WebSphere_Portal
   ```

   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configuring WebSphere Portal to use Oracle RAC
   This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:
- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon_(GSD), oracle listeners, and agents.
  - `$ gsdctl start`
  - `$ lsnrctl start`
  - `$ agentctl start`

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Next topic: Create users
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:
- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects:

   ```
   SQL> create user username identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   ```

   **Tip:** Balance the storage of user objects among tablespaces to prevent running out of space with overuse of `user_tablespace`. Also consider increasing the size of `user_tablespace` when handling a high volume of users.

2. Log in by entering the command `$ sqlplus` in SQL*Plus:

3. Enter the command `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

4. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults:

   ```
   SQL> create user releasusr identified by password;
   SQL> create user communityusr identified by password;
   SQL> create user customizationusr identified by password;
   SQL> create user jcr identified by password;
   ```

5. Connect to the content database by entering the command `SQL> connect`.

6. Enter the following, where `username` is an existing administrative user in the database. `user-name:username/password@dbname` For example, `system/manager@jcrdb` will log the administrative user system with a password of manager into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the `jcr` user, grant all necessary privileges. If you do not grant privileges, you will receive the error `ICMADMIN lacks CREATE SESSION Privilege logon denied when you try to connect with the jcruser`.

   ```
   SQL> create user jcr identified by password default tablespace users temporary tablespace temp;
   ```
8. Connect to the Feedback database:
   A. Enter the following command: `SQL> connect` 
   B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database. For example, `system/manager@fdbkdb` will log the administrative user `system` with a password of `manager` into the `fdbkdb` database.

9. Create the Feedback user: `SQL> create user feedback identified by password default tablespace users temporary tablespace temp;`

10. Connect to the LikeMinds database: `SQL> connect` 
11. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@lmdb` will log the administrative user `system` with a password of `manager` into the `lmdb` database.

12. Create the LikeMinds user: `SQL> create user lmdbusr identified by password default tablespace users temporary tablespace temp;`

13. Log out of the command line tool using the command `SQL> exit`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Installing Oracle RAC  
**Next topic:** Creating databases
Creating databases

View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal.

When creating Oracle RAC databases for use with WebSphere Portal, you should consider the following information:

- The Oracle RAC databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle RAC server will be remote or local to the WebSphere Portal installation.
- If using an earlier version of Oracle RAC (9i or earlier), ensure that Oracle RAC JVM is also installed.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle RAC database in order for WebSphere Portal to communicate with the IBM Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes are:

  - db_block_size = 8192 bytes
  - db_cache_size = 314,572,800 bytes
  - db_files = 1024 files
  - log_buffer = 65536 bytes
  - open_cursors = 1500 cursors
  - pga_aggregate_target = 209,715,200 bytes
  - pre_page_sga = true
  - processes = 300 processes
  - shared_pool_size = 209,715,200 bytes

  **Note:** If you are using IBM Java Content Repository, the open_cursors value may need to be increased based on the table count in the IBM Java Content Repository schema.

- **Prerequisites**
  - Create users

  Refer to the following instructions to create tablespaces:

  1. In the database directory, create the data directory data and the index directory index.
  2. Create the tablespaces. **Important:** You must use the same tablespace names listed in the commands. The tablespace names cannot be customized or modified.

    A. Find and edit the SQL script jcr_ora_tablespaces.sql in the directory wp_profile_root
       ./ConfigEngine/work/db/oracle.

    B. In the define section, replace the following variables with the values from your environment:

       - jcrdb
         - Name of the database you created to store user data.

       - logfile
         - Location to store the log file.

       - dbpath
         - Directory where you created the database.

    C. Set the size, autoextend, and maxsize values according to your environment. For example, you may want to change the maxsize to a set value rather than UNLIMITED. Consult your Database Administrator for more info.
D. Execute the following SQL script:

Notes:
- The DBA or a user with sufficient credentials (CREATE tablespace) must execute the script.
- The script will prompt for the database username and password.

```
# sqlplus
SQL > @jcr_ora_tablespaces.sql
```

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Create users
Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fbdkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`
- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`  
  - `customization` 
  - `community`  
  - `jcr` 
  - `feedback`  
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - `dbdomain.DbType`
- `dbdomain.DbName`
- `dbdomain.DbUrl`
- `dbdomain.DbSchema`

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.

   A. For `dbdomainDbType`, type `oracle`.
   
   B. For `dbdomainDbName`, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the `dbdomainDbUrl` property.
   
   C. For `dbdomainDbSchema`, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The `dbdomainDbName` should be the same value used for the `dbdomainDbSchema`

   **Restriction:** The value for `dbdomainDbSchema` must equal the value for `dbdomainDbUser`

   D. For `dbdomainDataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:

   - releaseDS
   - communityDS
   - customizationDS
   - jcrDS
   - lmdbDS
   - feedback

   E. For `dbdomainDbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note:

   - The database element of this value should match the value of `DbName`.
   - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
     `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

   F. For `dbdomainDbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomainDbUser` must equal the value for `dbdomainDbSchema`. 

   1671
G. For dbdomain.DbPassword, type the password for the database administrator.

H. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.

I. For dbdomain.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.

J. For dbdomain.DbHome, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For source.domain.DbType, type of the database you are currently configured to use. The value for source.domainDbType is Derby by default.

B. For source.domain.DbName, type the name of the database domain you are currently using.

C. For source.domain.DbSchema, type current schema identifier for objects within the database for this domain.

D. For source.domain.DataSourceName, type the name of the datasourse that is currently used in your IBM WebSphere Application Server configuration.

E. For source.domain.DbUrl, type the url currently used to access your database.

F. For source.domain.DbUser, type the name of the user accessing this database.

G. For source.domain.DbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_ddtype.properties.

A. For oracle.DbDriver, type the name of the class that SqlProcessor uses to import SQL files.

B. For oracle.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For oracle.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

**Prerequisites**
- Create users
- Creating databases
- Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.
2. Change to the directory `wp_profile_root/ConfigEngine`
3. To create the database users, type the following command:

   ```
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   '``WP_root\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql''.
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- Prerequisites
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.

2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '/dbpath./&jcrdb/data/&jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '/dbpath./&jcrdb/data/&jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '/dbpath./&jcrdb/data/&jcrdb._ICMVFP04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '/dbpath./&jcrdb/data/&jcrdb._ICMSFQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '/dbpath./&jcrdb/index/&jcrdb._ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   ```

   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.

   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.

   C. Refer to the Oracle command reference for more information about using the `create tablespaces` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Setting up databases  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `TABLESPACE` and a space. For example: `community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configuring WebSphere Portal to use Oracle RAC
Configuring WebSphere Portal to use Oracle RAC

This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- **Prerequisites**
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

**Tips:**

- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: `jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME`. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:
  
  ```
  jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521)) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICE_NAME))).
  ```

- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties:

```bash
./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
```

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

5. Transfer the database:

- **Note**: Do not execute the database-transfer task as a background process. This might cause the task to stall.

A. Change to the directory `wp_profile_root/ConfigEngine`.

B. Enter the following command:

```
./ConfigEngine.sh database-transfer -DWasPassword=password
```

**Note**: To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

```
SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);
```

7. Specify the JDBC URL to connect to the cluster:

A. Login to the WebSphere Application Server Administrator Console

B. Navigate to Resources > JDBC Providers

C. If there is a value in the Node field, remove it and click Apply.

D. For each Oracle JDBC provider, repeat the following steps:

1. Click the provider name.
2. Select Data Sources.
3. Click the name of the data source.
4. Under the Oracle data source properties, modify the URL attribute according to Oracle RAC configuration:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME))
```

5. Save your changes

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

**Parent topic**: Configuring WebSphere Portal to use Oracle RAC

**Previous topic**: Assigning custom table spaces
Configuring WebSphere Portal to use SQL Server

View information on installing and setting up SQL Server to work with WebSphere Portal.

1. Installing SQL Server
   View the steps to install SQL Server for use with WebSphere Portal.

2. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

3. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

4. Optional: Assigning custom filegroups
   The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

5. Configuring WebSphere Portal to use SQL Server 2005
   This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing SQL Server

View the steps to install SQL Server for use with WebSphere Portal.

Before you begin this task, complete the following prerequisites:

- You should have completed reviewing the Planning for SQL Server topic.
- You must install SQL Server separately from WebSphere Portal.
- WebSphere Portal requires either the DataDirect Connect for JDBC 3.7 JDBC driver or the Microsoft SQL Server JDBC Driver.
- You can obtain the DataDirect Driver from DataDirect Technologies. The JDBC driver consists of two parts: the JDBC driver libraries and JTA libraries. The JDBC driver libraries must be put on the WebSphere Portal system, while the JTA libraries are intended for SQL Server.
- You can obtain the Microsoft SQL Server JDBC Driver from Microsoft. See the Microsoft SQL Server product documentation for installation details.

The following section provides instructions for installing SQL Server for use with IBM® WebSphere® Application Server and WebSphere Portal. These steps are the same for both the DataDirect and Microsoft drivers unless noted.

1. Install SQL Server and all required patches.
2. Select the authentication mode for this installation:
   - Windows Authentication Mode
   - Mixed Mode (Windows Authentication and SQL Server Authentication)
     Either authentication mode allows the user who is specified as the database administrator in the wkplc_comp.properties file to log in to the SQL server. Mixed Mode authentication allows either a Windows user or a SQL server user, or both, to log in to the SQL Server.
3. In the SQL Server Setup panel, **Components to Install**, select the following components, which are required services for WebSphere Portal:
   - **SQL Server Database Services**
     - **Integration Services** The option **Integration Services**, creates the directory DTS/Binn, where you will need to copy files when you install Microsoft SQL Server JDBC drivers and enable XA connections.
4. Complete the installation using SQL Server documentation as a guide.
5. Enable TCP/IP connectivity in the **SQL Server Configuration Manager**.
6. Install the JDBC driver using one of these methods:
   - Installing DataDirect Connect for JDBC drivers on UNIX
   - Installing DataDirect Connect for JDBC drivers on Windows
   - Installing Microsoft SQL Server JDBC drivers and enabling XA connections
7. Network the connections for MSDTC in the Windows Component Services as described in Microsoft Help and Support.
8. Start SQL Server.

**Installing DataDirect Connect for JDBC drivers on UNIX**

1. Purchase and download DataDirect Connect for JDBC and save file 360connectjdbc.jar in a temporary work directory.
To create the required files, run the following command from the directory that contains 360connectjdbc.jar:

```
jar -xvf 360connectjdbc.jar
```

3. Run `./Installer.sh` in the same directory.

4. When installation is complete, change directory to `/installation/lib`, where `installation` is the directory in which you installed the DataDirect Connect for JDBC drivers.

5. Run the following command to change the permissions on the JAR files in the `installation/lib` directory:

```
chmod 777 *.jar
```

6. Change the ownership and group of these files by running the following commands in the `installation/lib` directory:

```
chgrp system_grp *.jar
chown root *.jar
```

Where `system_grp` is the system group as labeled by your operating system.

### Installing Microsoft SQL Server JDBC drivers and enabling XA connections

1. Download and install the Microsoft SQL Server JDBC driver.

2. Copy file `sqljdbc_xa.dll` from the `xa` subdirectory to the `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll` directory of the SQL Server installation.

3. Start the database server.

4. Ensure that the Distributed Transaction Coordinator has been started. The status can be verified in the list of services in the Computer Management console.

5. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.

6. Select **File > Open > File** and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.

7. Execute the script by selecting **Query > Execute**. **Note:** Any warnings that appear in the messages section of the application window that say that stored procedures cannot be found can be safely ignored.

8. For Microsoft SQL Server JDBC drivers: If you are running Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003, refer to the Registry Entries Are Required for XA Transaction Support document for information on a new security constraint and how to set SQL Server on Windows XP SP2, Windows XP 64-Bit Edition, or Windows Server 2003. Create a additional value in the Windows registry for WebSphere Portal by following these steps:

   A. Open the Windows Registry Editor (`regedit`) and navigate to the element `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XADLL`

   B. From the menu bar, select **Edit > New > String Value** to create a new parameter named `sqljdbc_xa.dll` in that element.

   C. Change the value of the new parameter to the location of the `sqljdbc_xa.dll` file copied in Step 2 above, for **example**: `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll`

Parent topic: Configuring WebSphere Portal to use SQL Server

Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing SQL Server

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
  - `release.DbName` = `release`
  - `jcr.DbName` = `jcrdb`
  - `feedback.DbName` = `fdbkdb`
  - `likeminds.DbName` = `lmdb`
  - `community.DbName` = `commdb`
  - `customization.DbName` = `custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - `dbdomain.DbType`
- dbdomain.DbName  
- dbdomain.DbUrl  
- dbdomain.DbSchema  

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomainDbType, type sqlserver2005.
   B. For dbdomain.DbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomain.DbUrl property.
   C. For dbdomain.DbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For dbdomain.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomain.DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should match the value of DbName.
   F. For dbdomain.DbUser, type the user ID for the database administrator.
   G. For dbdomain.DbPassword, type the password for the database administrator.
   H. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.
   I. For dbdomain.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.
   J. For dbdomain.DbHome, type the root location for the database. Note: This value is the location to store the database files locally.
   K. For dbdomain.AdminUrl, type the sqlserver URL without a database attached. This value is used to connect to the server for database administration operations.
   L. For dbdomain.DbHostName, type the hostname of the database.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. Important: The default values for the following parameters are
set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For source.domainDbType, type of the database you are currently configured to use. The value for source.domainDbType is Derby by default.

B. For source.domainDbName, type the name of the database domain you are currently using.

C. For source.domainDbSchema, type current schema identifier for objects within the database for this domain.

D. For source.domainDataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For source.domainDbUrl, type the url currently used to access your database.

F. For source.domainDbUser, type the name of the user accessing this database.

G. For source.domainDbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_dbtype.properties.

A. For sqlserver2005.DbDriver, type the name of the class that SqlProcessor uses to import SQL files.

B. For sqlserver2005.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For sqlserver2005.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

D. For sqlserver2005.DbConnectionPoolDataSource, type the name of the implementation class of the connection pool data source.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

- **Prerequisites**
  - Installing SQL Server
  - Modifying database properties

1. Change to the directory `wp_profile_root/ConfigEngine`
2. To create the databases, type the following command:
   ```bash
   ./ConfigEngine.sh create-database -DWasPassword=password
   ```
3. To create the database users, type the following command:
   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Modifying database properties

**Next topic:** Assigning custom filegroups

**Related tasks**
Create users and databases for SQL Server 2005 on AIX and UNIX
Assigning custom filegroups

The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin:

- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- For details on creating filegroups refer to the documentation for the database.

**Prerequisites**

- Installing SQL Server
- Modifying database properties
- Setting up databases

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

1. Determine the names of your custom filegroups.

2. Open the mapping file `wp_profile_root/PortalServer/config/tablespaces` that specifies the table space and index space for each property pairs for each database table:

   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.indexspace.indexspace`

   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword `ON` and a space. For example: `community.COMP_INST.tablespace=ON COMM8KSPACE`

   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,

   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
   - i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
Configuring WebSphere Portal to use SQL Server 2005

This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing SQL Server
  - Modifying database properties
  - Setting up databases

Tips:
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.
2. Enter the following commands to validate configuration properties:
   ```bash
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
   | WebSphere Application Server| ```bash
   .stopServer.sh server1 -username admin_userid -password admin_password
   ``` |
   | WebSphere Portal            | ```bash
   .stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ``` |
5. Transfer the database: **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory wp_profile_root/ConfigEngine.
B. Enter the following commands:

```
./ConfigEngine.sh database-transfer -DWasPassword=password
```

**Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. Change to the directory `wp_profile_root/bin`.

7. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

8. Update the SQL Server 2005 statistics for Portal, and JCR databases by opening SQL Server Management Studio, selecting `New Query`, and running the following query:

```
use db_name
exec sp_updatestats @resample='resample'
```

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Assigning custom filegroups
Verifying databases

After you configure IBM® WebSphere® Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

- Prerequisites
  - ▶️ Technotes for database connectivity issues

You can verify the database connection using IBM WebSphere Application Server or by opening WebSphere Portal in a browser.

- To verify that the WebSphere Portal application server is running by using WebSphere Application Server, complete these steps:
  1. Open the WebSphere Application Server administrative console by entering the following address in a browser:
     http://hostname.example.com:10027/ibm/console
     where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10027 is the default transport port that is created by WebSphere Application Server.
  2. Log into the administrative console.
  3. Depending on your version of WebSphere Application Server, click the appropriate option:
     - For WebSphere Application Server Version 6.1: Click Resources & JDBC Providers.
     - For WebSphere Application Server Version 7.0: Click Resources > JDBC > JDBC Providers
  4. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
  5. Select the name of the data source that is defined in wkplc_comp.properties. The default data source is wpdbDS.
  6. Select the name of the JDBC provider that is specified in wkplc_dbtype.properties. The default JDBC provider is wpdbJDBC_dbtype, where dbtype is replaced by the value that matches your environment.
  7. Click Test Connection to verify the database connection. If configuration parameters have been changed, you might need to restart WebSphere Application Server for the test to complete.

- To verify that the WebSphere Portal application server is running by opening WebSphere Portal in a browser, enter the following URL in a supported browser:
  http://hostname.example.com:10040/wps/portal
  where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10040 is the default transport port that is created by WebSphere Application Server.

Parent topic: Configure WebSphere Portal to use a remote database
Configuring the primary node to communicate with the deployment manager on Linux

After installing IBM® WebSphere® Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

- **Prerequisites**
  - Installing WebSphere Portal on Linux on the primary node
  - Configure WebSphere Portal to use a remote database

Perform the following steps to configure WebSphere Portal to communicate with the deployment manager:

1. Run the `.ConfigEngine.sh collect-files-for-dmgr -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory of the primary node, to create an archive or compressed file containing all the files which need to be copied to the Deployment Manager. **Note:** The archive or compressed file will be placed in the `wp_profile_root/filesForDmgr` directory and the file will be called `filesForDmgr.zip`.

2. Stop the deployment manager.

3. Expand the `filesForDmgr.zip` file into the installation root directory of the Deployment Manager; for example in the `opt/IBM/WebSphere/AppServer` directory. **Note:** If the Deployment Manager profile was not created in the default `AppServer/profiles/Dmgr01` directory, then the metadata_wkplc.xml file, located in the `AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml` directory in the zip file, must be placed into the correct Deployment Manager profile directory.

4. If the Deployment Manager profile is running on the same application server where WebSphere Portal is installed, remove the `com.ibm.ws.portletcontainer.deploytask_6.1.5.jar` file from the `AppServer\plugins` directory.

5. Start the deployment manager.

**Parent topic:** Preparing the primary node on Linux

**Previous topic:** Configure WebSphere Portal to use a remote database

**Next topic:** Removing search collections on Linux

**Related tasks**

Configuring Portal Search in a cluster on Linux
Removing search collections on Linux

If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

Prerequisites
- Installing WebSphere Portal on Linux on the primary node
- Configure WebSphere Portal to use a remote database
- Configuring the primary node to communicate with the deployment manager on Linux

Perform the following step to remove the search collection:

Perform the following steps to delete all existing search collections from the primary node:
1. Log on to WebSphere Portal.
2. Navigate to Administration > Search Administration > Manage Search and then click Search Collections.
3. Click the Delete Collection icon for each search collection and then click OK until they are all deleted.
4. Restart the WebSphere_Portal server and then navigate back to the Search Collections page to verify that all search collections have been deleted.

Parent topic: Preparing the primary node on Linux
Previous topic: Configuring the primary node to communicate with the deployment manager on Linux
Choosing the type of cluster to create on Linux

If you installed a IBM® WebSphere® Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux

Choose one of the following options to create a cluster:

- **Creating a static cluster on Linux**
  After installing IBM WebSphere Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

- **Creating a new dynamic cluster on Linux using WebSphere Virtual Enterprise**
  After installing and configuring IBM WebSphere Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

**Parent topic:** Setting up a cluster on Linux

**Previous topic:** Preparing the primary node on Linux

**Next topic:** Preparing a remote Web server when portal is installed on Linux
Creating a static cluster on Linux

After installing IBM® WebSphere® Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

Perform the following steps to create the cluster:

1. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.

   **Important:** Ensure that you set WasUserId and WasPassword to the Deployment Manager user ID and password.

2. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:

   **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.

   A. Set WasSoapPort to the port used to connect remotely to the deployment manager.
   B. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
   C. Verify that WasPassword is set to your deployment manager password.
   D. Verify that PortalAdminPwd is set to your WebSphere Portal password.
   E. Verify thatClusterName is set.
   F. Verify that PrimaryNode is set to true.

3. Make a backup copy of the wp_profile_root/config/cells/cell_name/wim/config/wimconfig.xml and wp_profile_root/config/cells/cell_name/wim/model/wimxmlextension.xml, if available, files.

4. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.

   **Note:** If you want to specify custom ports for the nodeagent, add the -DPortPropsFile=full to portsfile parameter to the cluster-node-config-pre-federation task. You can use the ports files that are found on the Setup CD for WebSphere_Portal and server1 as a guide.

   **Note:** You may receive a message about accepting an SSL signer certificate. Failure to accept the SSL signer certificate will cause the script to fail. Alternatively, the com.ibm.ssl.enableSignerExchangePrompt flag can be enabled in the ssl.client.props file for “DefaultSSLSettings” in order to allow acceptance of the signer during the connection attempt.

   **Warning:** If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:

   A. Remove the node if the AddNode task succeeded.
   B. Log on to the deployment manager and perform the following steps if the items exist:
      1. Remove all enterprise applications.
      2. Remove the WebSphere_Portal server definition.
      3. Remove the WebSphere Portal JDBC Provider.

   **Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following technote: Migrating with Lookaside Data.
Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `laDbType` if using a property extension database in the `wkplc.properties` file.
   
   **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db DbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DvmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

   **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

6. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task.

9. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:

   - Configuring a Web server and an application server on separate machines (remote)
   - Configuring a Web server and an application server profile on the same machine
   - Configuring a Web server and a deployment manager profile on the same machine

   **Note:** Start with the step about launching the Plug-ins installation wizard.

10. Perform the following steps to access the Web Content Management content through an external Web server:

    A. Log on to the deployment manager administrative console.
B. Select Environment > WebSphere Variables.

C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.

D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.

G. Log off of the deployment manager administrative console.

11. Run the following tasks to propagate your changes:Note: WebSphere_Portal_nodename is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the serverstatus -all task to get a list of the server names and their status.

   A. ./stopManager.sh -username admin_userid -password admin_password, from the dmgr_profile_root\bin directory

   B. ./stopNode.sh -username admin_userid -password admin_password, from the wp_profile_root/bin directory

   C. ./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password

   D. ./startManager.sh, from the dmgr_profile_root\bin directory

   E. ./startNode.sh, from the wp_profile_root/bin directory

   F. ./startServer.sh WebSphere_Portal_nodename

12. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**Parent topic:** Choosing the type of cluster to create on Linux

**Related tasks**

- Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Creating a new dynamic cluster on Linux using WebSphere Virtual Enterprise

After installing and configuring IBM® WebSphere® Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

Before creating your dynamic cluster, install and configure the Deployment Manager and perform all the tasks under “Preparing the primary node.” On the Deployment Manager system, install WebSphere Virtual Enterprise and augment the deployment manager profile. On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- **Prerequisites**
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
    - Augmenting profiles

Perform the following steps to create a dynamic cluster:

1. Perform the following steps for on the primary node of the dynamic cluster:
   A. Prepare the node for the dynamic cluster; perform all tasks under Preparing the primary node.
   B. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   C. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
      1. Set WasSoapPort to the port used to connect remotely to the deployment manager.
      2. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
      3. Verify that WasPassword is set to your deployment manager password.
      4. Verify that PortalAdminPwd is set to your WebSphere Portal password.
      5. Verify that ClusterName is set.
      6. Verify that PrimaryNode is set to true.
   D. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.

   **Warning:** If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:
   1. Remove the node if the AddNode task succeeded.
   2. Log on to the deployment manager and perform the following steps if the items exist:
      A. Remove all enterprise applications.
      B. Remove the WebSphere_Portal server definition.
      C. Remove the WebSphere Portal JDBC Provider.

   **Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following
technote: Migrating with Lookaside Data.

E. Run the following task. Include each node name as a comma separated list in the command:

1. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the wkplc.properties file. **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the wkplc.properties file on the primary node.

2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

F. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

G. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=dmgr_password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-dynamic-cluster-setup` task completes.

After running the `wp-change-portal-admin-user` task, start or restart the WebSphere Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager cell before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

2. Log on to the deployment manager administrative console.

3. Perform the following steps to create a node group:
   A. Click **System administration > Node groups**.
   B. Click **New**.
   C. Type the node group **Name**.
   D. Optional: Type any information about the node group in the **Description** text box.
   E. Click **OK**.
   F. Click the **Save** link to save your changes to the master configuration.

4. Perform the following steps to add members to the node group:
   A. Click **System administration > Node groups**.
   B. Click on the name of the node group that you want to add members to.
   C. Click **Node group members** under Additional Properties.
   D. Click **Add**.
   E. Select the primary node and then click **Add**.
   F. Click the **Save** link to save your changes to the master configuration.

5. Perform the following steps to create a dynamic cluster in the node group:
   A. Click **Servers > Dynamic clusters**.
   B. Click **New**.
C. Select WebSphere Application Server from the Server Type pull-down menu and then click Next.
D. Type the cluster name in the Dynamic cluster name text box and then click Next. Type the same value that you provided for the ClusterName parameter in the wkplc.properties file of your primary node.
E. Remove all default membership policies and then click Subexpression builder.
F. Enter the following information in the Subexpression builder window:
   1. Select and from the Logical operator pull-down menu.
   2. Select Nodegroup from the Select operand pull-down menu.
   3. Select Equals (=) from the Operator pull-down menu.
   4. Type the nodegroup name you created in the previous step in the Value text box.
   5. Click Generate subexpression.
   6. Click Append.
G. Click Preview membership to verify that all nodes included in the nodegroup display and then click Next.
H. Click the Create the cluster member using an existing server as a template radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu.
I. Click Next.
J. Specify the dynamic cluster properties and then click Next.
K. Review the summary page to verify your actions and then click Finish.
L. Click the Save link to save your changes to the master configuration.

6. Define or verify the following parameters in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   A. Set ClusterName to the name of the new dynamic cluster.
   B. Verify that CellName is set to the deployment manager cell.
   C. Verify that NodeName is set to the local WebSphere Portal node.
   D. Set ServerName to the server that will be used for the dynamic cluster member on this node.
      Note: Log on to the deployment manager administrative console and click Dynamic Clusters > PortalCluster > Dynamic cluster members to find the name of the server used for the dynamic cluster.
   E. Verify that PrimaryNode is set to true.

7. Run the ./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the dynamic cluster.
   Note: This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

8. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node-nodename, Server-servername option to narrow the scope of the listed variables, where Node-nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Reresynchronize.
   G. Log off of the deployment manager administrative console.

9. Run the following tasks to propagate your changes:
   Note: WebSphere_Portal_nodename is the name of the node's WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the
server name, run the `serverstatus -all` task to get a list of the server names and their status.

A. `.stopManager.sh -username admin_userid -password admin_password`, from the `dmgr_profile_root\bin` directory

B. `.stopNode.sh -username admin_userid -password admin_password`, from the `wp_profile_root/bin` directory

C. `.stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`

D. `.startManager.sh`, from the `dmgr_profile_root\bin` directory

E. `.startNode.sh`, from the `wp_profile_root/bin` directory

F. `.startServer.sh WebSphere_Portal_nodename`

**Parent topic:** Choosing the type of cluster to create on Linux
Preparing a remote Web server when portal is installed on Linux

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on Linux
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to on; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server documentation</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>See the appropriate Apache Server documentation</td>
<td>AllowEncodedSlashes directives</td>
</tr>
</tbody>
</table>

4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

**If using WebDAV:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to true.

**Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.
Configuring WebSphere Portal to use a user registry on Linux in a clustered environment

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux

Perform the following tasks to configure WebSphere Portal to use a user registry:

- **Preparing user registries on Linux**
  Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

- **Choosing your user registry model on Linux in a clustered environment**
  Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

**Parent topic:** Setting up a cluster on Linux

**Previous topic:** Preparing a remote Web server when portal is installed on Linux

**Next topic:** Preparing additional nodes on Linux
Preparing user registries on Linux

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

Choose the appropriate LDAP server to install and setup:

- **Preparing a Domino Directory server**
  If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a SecureWay Security Server**
  If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Novell eDirectory**
  If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Sun Java System Directory Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Tivoli Directory Server**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

**Parent topic:** Configuring WebSphere Portal to use a user registry on Linux in a clustered environment
Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Domino Directory:

1. Perform the following steps to install the Domino Directory:
   A. Go to Lotus Domino documentation.
   B. Select the appropriate version tab for your product.
   C. Click the Download/View online link for the Lotus Domino for multiple platforms Information Center.
   D. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > Server installation > Installing Domino on Linux and perform this task.
   E. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > The Domino server setup program and perform this task.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Navigate to the People view of the Domino Directory and then click Add Person.
   B. Enter the following values in the New Person form to create the wpsbind user:
      - Last Name
        - wpsbind
      - User Name
        - wpsbind/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsbind
      - Internet password
        - wpsbind
   C. Click Save and Close to save the new person record for wpsbind and return to the People view.
   D. Click Add Person and enter the following values in the New Person form to create the wpsadmin user:
      - Last Name
        - wpsadmin, where wpsadmin in the user ID for the WebSphere Portal Administrator
      - User Name
        - wpsadmin/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsadmin
      - Internet password
        - wpsadmin
   E. Click Save and Close to save the new person record for wpsadmin and return to the People view.
   F. Navigate to the Groups view and click Add Group.
   G. Enter the following values in the New Group form on the Basic tab:
      - Group name
Note: If you plan to configure WebSphere Portal for multiple user registries and your Lotus Domino LDAP will share a realm with another user registry, you must use the hierarchical naming convention for the group names, for example: wpsadmins/DominoDomain, to avoid unexpected results during WebSphere Portal runtime.

- **Group type**
  - Multi-purpose

- **Members**
  - wpsbind/DominoDomain
  - wpsadmin/DominoDomain

  **Note:** You can add additional administrator users if required.

H. Click **Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

3. Perform the following steps to update the access control list for the Domino Directory:
   A. Open the names.nsf file in the Lotus Domino Administrator or Lotus Notes client.
   B. Click **File > Application > Access Control** from the main menu to open the access control list for the file.
   C. In the **Access Control List > Basics** panel, ensure that the wpsadmins group has either Author or Editor access.
   D. Add the following Role Types to the wpsadmins group:
      - GroupCreator
      - GroupModifier
      - UserCreator
      - UserModifier
   E. Click **OK**.

**Parent topic:** Preparing user registries on Linux
Preparing a SecureWay Security Server

If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare SecureWay Security Server:

1. Install SecureWay Security Server; refer to the IBM SecureWay™ Security Server for z/OS® and OS/390® for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   
   A. Optional: Perform the following steps to create a new directory suffix:
      
      1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
      2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3. Type the **Base DN** name for the suffix; for example: \texttt{dc=yourcompany,dc=com}.
      4. Click **Add**.
      5. Click **OK** to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      
      - Use the **PortalUsers.ldif** file as a working example and adapted appropriately to work with your LDAP server.
      - Use the **ContentUsers.ldif** file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every \texttt{dc=yourco,dc=com} with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to **accessGroup**. If using Tivoli Access Manager Version 6, set the **objectclasses** to **groupOfNames**.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on Linux
Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Novell eDirectory:

1. Install Novell eDirectory; refer to eDirectory for information.
2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on Linux
Preparing a Sun Java System Directory Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.

2. Perform the following steps to create the WebSphere Portal administrative user:

   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
      2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4. Click **Add**.
      5. Click **OK** to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the **PortalUsers.ldif** file as a working example and adapted appropriately to work with your LDAP server.
      - Use the **ContentUsers.ldif** file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
      C. Replace every `dc=yourco,dc=com` with your suffix.
      D. Replace any prefixes and suffixes that are unique to your LDAP server.
      E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
      F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to **accessGroup**. If using Tivoli Access Manager Version 6, set the **objectclasses** to **groupOfNames**.
      G. Save your changes.
      H. Follow the instructions provided with your directory server to import the LDIF file.
      I. Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on Linux
Preparing a Tivoli Directory Server

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

   
   **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:
   
   A. Optional: Perform the following steps to create a new directory suffix:
      
      1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
      2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
      3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
      4. Click **Add**.
      5. Click **OK** to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      
      - Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.
      - Use the `ContentUsers.ldif` file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every `dc=yourco,dc=com` with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the `objectclasses` to `accessGroup`. If using Tivoli Access Manager Version 6, set the `objectclasses` to `groupOfNames`.

   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

**Parent topic:** Preparing user registries on Linux
Choosing your user registry model on Linux in a clustered environment

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on Linux in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on Linux in a clustered environment**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

- **Adapting the attribute configuration**
  After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

Parent topic: Configuring WebSphere Portal to use a user registry on Linux in a clustered environment
Configuring a stand-alone LDAP user registry on Linux in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on Linux in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on Linux in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on Linux in a clustered environment
Configuring a stand-alone LDAP user registry on Linux in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the wp-modify-ldap-security task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the standalone.ldap.realm parameter or you can set ignoreDuplicateIDs=true in the wkplc.properties file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Standalone LDAP configuration heading:

   - standalone.ldap.id
   - standalone.ldap.host
   - standalone.ldap.port
   - standalone.ldap.blindDN
   - standalone.ldap.bindPassword
   - standalone.ldap.idapServerType
   - standalone.ldap.userIdMap
   - standalone.ldap.groupIdMap
   - standalone.ldap.groupMemberIdMap
   - standalone.ldap.userFilter
   - standalone.ldap.groupFilter
   - standalone.ldap.serverId
   - standalone.ldap.serverPassword
   - standalone.ldap.realm
   - standalone.ldap.primaryAdminId
   - standalone.ldap.primaryAdminPassword
   - standalone.ldap.primaryPortalAdminId
   - standalone.ldap.primaryPortalAdminPassword
   - standalone.ldap.primaryPortalAdminGroup
   - standalone.ldap.baseDN
3. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.idap.et.group.objectClasses
   - standalone.idap.et.group.objectClassesForCreate
   - standalone.idap.et.group.searchBases
   - standalone.idap.et.personaccount.objectClasses
   - standalone.idap.et.personaccount.objectClassesForCreate
   - standalone.idap.et.personaccount.searchBases

4. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attributes heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.idap.gm.groupMemberName
   - standalone.idap.gm.objectClass
   - standalone.idap.gm.scope
   - standalone.idap.gm.dummyMember

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the wkplc.properties file under the Default parent, RDN attribute heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - standalone.idap.personAccountParent
   - standalone.idap.groupParent
   - standalone.idap.personAccountRdnProperties
   - standalone.idap.groupRdnProperties

6. Save your changes to the wkplc.properties file.

7. Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. Note: See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.
   - WcmContentAuthorsGroupId
   - WcmContentAuthorsGroupCN

8. Run the ./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry.
   Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

9. Run the ./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to set the stand-alone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Run the ./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to check that all defined attributes are available in the configured LDAP user registry. Important: When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. **Edit the** `wp_profile_root` /PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. **Add the following lines to the file:**

```plaintext
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. **Save your changes and close the file.**

D. **Run the** `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWenPassword=password` task, located in the `wp_profile_root`/ConfigEngine directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: *Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management*

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on Linux in a clustered environment

**Related tasks**
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring a stand-alone LDAP user registry over SSL on Linux in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL:

Using the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:

   • **Server trust store**
     
     A. Add the certificate to the trust store:
     
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: NodeDefaultSSLSettings
           - Clustered environments: CellDefaultSSLSettings
        
           **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
        4. Click Key stores and certificates.
        5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
        6. Click Signer certificates, click Add, and then enter the following information:
           - Type the Alias the key store uses for the signer certificate.
           - Type the File name where the signer certificate is located.
        7. Click OK and then click Save to save the changes to the master configuration.

   B. Retrieve the certificate from the port:
     
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: NodeDefaultSSLSettings
Clustered environments: CellDefaultSSLSettings

Clustered environments: Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

4. Click Key stores and certificates.

5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.

6. Click Signer certificates, click Retrieve from port, and then enter the following information:
   - Type the Host name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL Port used when attempting to retrieve the signer certificate.
   - Type the Alias the key store uses for the signer certificate.

7. Click Retrieve signer information to retrieve the certificate from the port.

8. Click OK and then click Save to save the changes to the master configuration.

Client trust store Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

A. See Secure installation for client signer retrieval.

B. Run the retrieveSigners task from the wp_profile_root/bin directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

C. Update the trust store properties file:
   1. Use a text editor to open the ssl.client.props file, located in the wp_profile_root/properties directory.
   2. Change the com.ibm.ssl.trustStore parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter

```
com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12
```

   to use the default trust store.

   3. Save your changes.

2. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Stand-alone LDAP configuration heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - standalone.idap.id
   - standalone.idap.host
   - standalone.idap.port
   - standalone.idap.blindDN
   - standalone.idap.bindPassword
   - standalone.idap.idapServerType
   - standalone.idap.userldMap
   - standalone.idap.groupldMap
   - standalone.idap.groupMemberldMap
   - standalone.idap.userFilter
   - standalone.idap.groupFilter
   - standalone.idap.serverId
   - standalone.idap.serverPassword
   - standalone.idap.realm
   - standalone.idap.primaryAdminId
   - standalone.idap.primaryAdminPassword
   - standalone.idap.primaryPortalAdminId
4. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.et.group.objectClasses`
   - `standalone.ldap.et.group.objectClassesForCreate`
   - `standalone.ldap.et.group.searchBases`
   - `standalone.ldap.et.personaccount.objectClasses`
   - `standalone.ldap.et.personaccount.objectClassesForCreate`
   - `standalone.ldap.et.personaccount.searchBases`

5. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.gm.groupMemberName`
   - `standalone.ldap.gm.objectClass`
   - `standalone.ldap.gm.scope`
   - `standalone.ldap.gm.dummyMember`

6. Required: Enter a value for the following required relative distinguished name (RDN) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading. **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.personAccountParent`
   - `standalone.ldap.groupParent`
   - `standalone.ldap.personAccountRdnProperties`
   - `standalone.ldap.groupRdnProperties`

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL). **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   Required parameters:
   - `standalone.ldap.sslEnabled`
   - `standalone.ldap.sslConfiguration`

   Optional parameters:
   - `standalone.ldap.certificateMapMode`
   - `standalone.ldap.certificateFilter`

8. Save your changes to the `wkplc.properties` file.

9. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry. **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press `y` then `Enter`.

10. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set the stand-alone LDAP user registry.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: **Starting and stopping servers, deployment managers, and node agents.**

12. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured...
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on Linux in a clustered environment

**Related tasks**

- Enabling LDAP security after cluster creation
Configuring the default federated repository on Linux in a clustered environment

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on Linux in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on Linux in a clustered environment**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on Linux in a clustered environment**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

**Parent topic:** Choosing your user registry model on Linux in a clustered environment
Configuring a federated LDAP user registry on Linux in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Adding an LDAP user registry on Linux in a clustered environment**
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName,o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

- **Adding an LDAP user registry over SSL on Linux in a clustered environment**
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

Parent topic: Configuring the default federated repository on Linux in a clustered environment
Adding an LDAP user registry on Linux in a clustered environment

Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM® Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName, o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.id`
   - `federated.ldap.host`
   - `federated.ldap.port`
   - `federated.ldap.bindDN`
   - `federated.ldap.bindPassword`
   - `federated.ldap.ldapServerType`
   - `federated.ldap.baseDN`

3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

   - `federated.ldap.et.group.objectClasses`
   - `federated.ldap.et.group.objectClassesForCreate`
   - `federated.ldap.et.group.searchBases`
   - `federated.ldap.et.personaccount.objectClasses`
4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attribute heading: 
   
   - `federated.ldap.gm.groupMemberName`  
   - `federated.ldap.gm.objectClass`  
   - `federated.ldap.gm.scope`  
   - `federated.ldap.gm.dummyMember`  

   `Note:` See the properties file for specific information about the required parameters and for advanced parameters.

5. Save your changes to the `wkplc.properties` file.

6. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. 
   
   - `WcmContentAuthorsGroupId`  
   - `WcmContentAuthorsGroupCN`  

   `Note:` See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.

7. Run the `./ConfigEngine.sh validate-federated-ldap -DWasPassword=password` task to validate your LDAP server settings. 

   `Attention:` If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry.

   `Note:` During the validation task, you may receive the following prompt: `Add signer to the trust store now?`. Press `y` then `Enter`.

8. Run the `./ConfigEngine.sh wp-create-ldap -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add an LDAP user registry to the default federated repository. 

   `Note:` Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: `Starting and stopping servers, deployment managers, and node agents`.

10. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:

    A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

    B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:

    - `id`  
    - `baseDN`  
    - `nameInRepository`  

    `Note:` See the properties file for specific information about the required parameters and for advanced parameters.

    C. Save your changes to the `wkplc.properties` file.

    D. Run the `./ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to create a base entry in a repository.

    E. Stop and restart all necessary servers to propagate your changes.

11. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

12. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

13. Perform the following steps to update the user registry where new users and groups are stored:

**Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

**Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

**Note:** See the properties file for specific information about the required parameters and for advanced parameters.

- `personAccountParent`
- `groupParent`
- `personAccountRdnProperties`
- `groupRdnProperties`

The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

- `personAccountParent=dc=yourco,dc=com`
- `groupParent=dc=yourco,dc=com`

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=yourpassword` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for `realmName` or leave blank to update the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=yourpassword` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=yourpassword` task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

B. Add the following lines to the file:

```properties
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```
Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management.

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

16. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

17. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   **Important:**
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

   **Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

   A. Run the following task from the `wp_profile_root/ConfigEngine directory`: `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.

   B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere Portal servers. In a standalone environment, restart the server1 and WebSphere Portal servers.

   C. Run the following task from the `wp_profile_root/ConfigEngine directory`: `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupid` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere Portal servers. In a standalone environment, restart the server1 and WebSphere Portal servers.
18. **Optional:** **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

Adding an LDAP user registry over SSL on Linux in a clustered environment

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `/wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
       1. Log in to the WebSphere Application Server Administrative Console.
       2. Navigate to Security > SSL certificate and key management > SSL configurations.
       3. Click the appropriate SSL configuration from the list. For example,
         - Stand-alone environments: `NodeDefaultSSLSettings`
         - Clustered environments: `CellDefaultSSLSettings`

         **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

       4. Click **Key stores and certificates**.
       5. Click the appropriate trust store from the list; for example, `NodeDefaultTrustStore`.
       6. Click **Signer certificates**, click **Add**, and then enter the following information:
          - Type the Alias the key store uses for the signer certificate.
          - Type the File name where the signer certificate is located.
       7. Click **OK** and then click **Save** to save the changes to the master configuration.

   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
2. Navigate to Security > SSL certificate and key management > SSL configurations.
3. Click the appropriate SSL configuration from the list. For example,
   - Stand-alone environments: NodeDefaultSSLSettings
   - Clustered environments: CellDefaultSSLSettings

   **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
4. Click Key stores and certificates.
5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
6. Click Signer certificates, click Retrieve from port, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.
7. Click Retrieve signer information to retrieve the certificate from the port.
8. Click OK and then click Save to save the changes to the master configuration.

   **Client trust store Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.
   A. See Secure installation for client signer retrieval.
   B. Run the retrieveSigners task from the wp_profile_root/bin directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. **Note:** This task might report an error, but it does successfully update the trust store. You can ignore the error message.
   C. Update the trust store properties file:
      1. Use a text editor to open the ssl.client.props file, located in the wp_profile_root/properties directory.
      2. Change the com.ibm.ssl.trustStore parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12 to use the default trust store.
      3. Save your changes.
   2. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

   3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
      - federated.idap.id
      - federated.idap.host
      - federated.idap.port
      - federated.idap.blindDN
      - federated.idap.blindPassword
      - federated.idap.idapServerType
      - federated.idap.idap.baseDN

   4. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
      - federated.idap.et.group.objectClasses
      - federated.idap.et.group.objectClassesForCreate
      - federated.idap.et.group.searchBases
5. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attribute heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
- federated.ldap.et.personaccount.objectClasses
- federated.ldap.et.personaccount.objectClassesForCreate
- federated.ldap.et.personaccount.searchBases

6. Enter a value for the following parameters to enable Secure Socket Layers (SSL): Note: See the properties file for specific information about the required parameters and for advanced parameters.
   Required parameters:
   - federated.ldap.gm.groupMemberName
   - federated.ldap.gm.objectClass
   - federated.ldap.gm.scope
   - federated.ldap.gm.dummyMember

   Optional parameters:
   - federated.ldap.certificateMapMode
   - federated.ldap.certificateFilter

7. Save your changes to the wkplc.properties file.

8. Run the ./ConfigEngine.sh validate-federated-ldap -DWasPassword=password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry. Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

9. Run the ./ConfigEngine.sh wp-create-ldap -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add an LDAP user registry to the default federated repository. Note: Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:
      Note: See the properties file for specific information about the required parameters and for advanced parameters.
      - id
      - baseDN
      - nameInRepository
   C. Save your changes to the wkplc.properties file.
   D. Run the ./ConfigEngine.sh wp-create-base-entry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to create a base entry in a repository.
E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root`/ConfigEngine directory, to list the names and types of configured repositories.

13. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root`/ConfigEngine directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

14. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root`/ConfigEngine directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root`/ConfigEngine directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

   **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` command.
task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `.ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password task`, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standaloneldap.realm</code> in the wkplc.properties file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the wkplc.properties file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

17. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

18. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

**Important:**
- Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
- Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root/ConfigEngine` directory: `.ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword` **Important:** You must provide the full distinguished name (DN) for the `newAdminid` parameter.

B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine` directory: `.ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` **Important:** You must provide the full distinguished name (DN) for the `newAdminid` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server server instance. If the
D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

19. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it. The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a federated LDAP user registry on Linux in a clustered environment

- Enabling LDAP security after cluster creation

**Related Information**
- User IDs and passwords
Adding a database user registry on Linux in a clustered environment

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you have WebSphere Application Server Version 7.0.x installed, you must install APAR PM23090 and APAR PM24181 for WebSphere Portal prior to running this task. Clusters with WebSphere Application Server Version 6.1.x do not require these APARs.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_DB.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_DB.properties` helper file.

1. Set up a new database, including creating a new user with appropriate database privileges for accessing the database:

   **Instructions for setting up databases:** Refer to the appropriate documentation for the type of database you want to set up.

   **Consulting your database administrator:** The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

   **Table 1. Steps for creating a new database to use as a database user registry.**

<table>
<thead>
<tr>
<th>Database</th>
<th>Steps</th>
</tr>
</thead>
</table>

   1736
### DB2

Perform the following steps to create a DB2 database:

1. **Install DB2.**
2. **Enter the following database tuning commands:**
   ```
   CREATE DB dbname using codeset UTF-8
territory us PAGESIZE 8192
   
   UPDATE DB CFG FOR dbname USING
   appheapsz 4096
   
   UPDATE DB CFG FOR dbname USING
   app_ctl_heap_sz 1024
   
   UPDATE DB CFG FOR dbname USING
   stmtheap 32768
   
   UPDATE DB CFG FOR dbname USING
   dbheap 2400
   
   UPDATE DB CFG FOR dbname USING
   locklist 1000
   
   UPDATE DB CFG FOR dbname USING
   logfilsiz 4000
   
   UPDATE DB CFG FOR dbname USING
   logprimary 12
   
   UPDATE DB CFG FOR dbname USING
   logsecond 20
   
   UPDATE DB CFG FOR dbname USING
   logbufsz 32
   
   UPDATE DB CFG FOR dbname USING
   avg_appls 5
   
   UPDATE DB CFG FOR dbname USING
   locktimeout 30
   
   UPDATE DB CFG FOR dbname using
   AUTO_MAINT off
   ```

### Oracle

Perform the following steps to create an Oracle database:

1. **Install Oracle using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.**
2. Configure the database in Dedicated Server Mode.
3. Enter the recommended initial buffer pool sizes or set them according to your business needs:
   - `db_block_size = 8192`
   - `db_cache_size = 300M`
   - `db_files = 1024`
   - `log_buffer = 65536`
   - `open_cursors = 1500`
   - `pga_aggregate_target = 200M`
   - `pre_page_sga = true`
   - `processes = 300`
   - `shared_pool_size = 200M`

### SQL Server

Perform the following steps to create an SQL Server database:

1. **Install SQL Server.**
2. **Set Collation to case-sensitive.**
3. **Note:** Install SQL Server with the appropriate portal database collation so that your tempdb collation setting matches the collation you use for the property extension database. The tempdb collation is inherited from the master database, which you set when you install SQL Server.

2. Perform the following steps to define the **DbDriver** and **DbLibrary** parameter values:
   - Navigate to the following directory: `wp_profile_root/ConfigEngine/properties`
   - Locate and open `wkplc_dbtype.properties` with any text editor.
   - Enter a value for the following parameters under the appropriate database type properties heading:
     - `db_type.DbDriver`
     - `db_type.DbLibrary`
   - Save your changes.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated Database Properties heading:**Note:** See the properties file for specific information about the required parameters and for advanced parameters.
1. Navigate to the following directory: `wp_profile_root/properties`
2. Locate and open `soap.client.props` with any text editor.
3. Locate the `com.ibm.SOAP.requestTimeout` parameter and change the value to 1000.
4. Save and close `soap.client.props`.

5. Perform the following steps in a clustered environment:
   A. Run the `./ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=password -DDbDomain=federated.db -Db_type.DmgrDbLibrary=local path of the database jars on the Deployment Manager -DDmgrNodeName=dmgr_node_name` task from the `wp_profile_root/ConfigEngine` directory to create the local Deployment Manager WebSphere variable used to access the database jars.
   
   **Note:** The `db_type` in `db_type.DmgrDbLibrary` should be set to the type of database you are using, for example `db2`. The **local full path of the database jars on the Deployment Manager** should be one of the following options:

   - `DB2 Type 2 driver`: `db2java.zip`
   - `DB2 Type 4 driver`: `db2jcc.jar;db2jcc_license_cu.jar`
   - `DB2 for z/OS Type 2 driver`: `db2java.zip`
   - `DB2 for z/OS Type 4 driver`: `db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc_javax.jar`
   - `Oracle`: `ojdbc14.jar`
   - `SQL Server JDBC driver provided by Microsoft`: `sqljdbc.jar`
   - `SQL Server JDBC driver provided by DataDirect`: `sqlserver.jar;base.jar;util.jar`

   B. Run the following task. Include each node name as a comma separated list in the command:

   **Running the task:** You do not have to run this task more than once. You can run this task from any node in the cluster.

   1. Set the property value for `federated.db.DbType` in the `wkplc.properties` file if using a database user registry.
   2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=password -DDbDomain=federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory on each node to create the variable used to access the VMM database jars.

   **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

   C. Stop and restart all necessary servers to propagate your changes.

6. Stop and restart all necessary servers to propagate your changes.

7. Run the `./ConfigEngine.sh wp-create-db -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to add a database user registry to the default federated repository. **Note:** Users who are not in an LDAP do
not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `. /ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the `. /ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

**Parent topic:** Configuring the default federated repository on Linux in a clustered environment

**Related tasks**

Starting and stopping servers, deployment managers, and node agents

Enabling LDAP security after cluster creation
Adding realm support on Linux in a clustered environment

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - realmName
   - securityUse
   - delimiter
   - addBaseEntry
3. Save your changes to the wkplc.properties file.
4. Run the ./ConfigEngine.sh wp-create-realm -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add a new realm to the Virtual Member Manager configuration. Important: To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the wkplc.properties file with the base entry information and rerun the wp-create-realm task. Repeat these steps until all realms are created.
5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.
6. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading and then save your changes:Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - realmName
   - realm.personAccountParent
   - realm.groupParent
   - realm.orgContainerParent
7. Run the ./ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to update the default parents per entity type and realm. Important: Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types.
and realms.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:
   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
      - realmName
      - addBaseEntry
   C. Save your changes to the wkplc.properties file.
   D. Run the ./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add additional LDAP base entries to the realm configuration.
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:
   A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.
   B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.
   C. Create a new group in the Manage Users and Groups portlet to replace the current group.
   D. Run the ./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminId
       -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task, from the wp_profile_root/ConfigEngine directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.
   E. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
   F. Run the ./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminId
       -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid task to replace the old WebSphere Portal administrative user ID and group ID with the new user and group. **Important:** You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.
   G. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
   H. Optional: Perform the following steps to set the realm you created as the default realm: **Remember:** Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the wp-query-realm-baseentry task to see what base entries are part of the default realm. If the default realm is missing
the base entry, run the `wp-add-realm-baseentry` task to add the base entry to the default realm.

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. For `defaultRealmName`, type the `realmName` property value you want to use as the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `.ConfigEngine.sh wp-default-realm -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set this realm as the default realm.

E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. For `realmName`, type the name of the realm you want to query.

C. Save your changes to the `wkplc.properties` file.

D. Run the `.ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for `realmName` or leave blank to update the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `.ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `.ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

Adapting the attribute configuration

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. Querying the defined attributes on Linux
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. Adding attributes on Linux in a clustered environment
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. Mapping attributes on Linux in a clustered environment
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. Removing attributes
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Parent topic: Choosing your user registry model on Linux in a clustered environment

Related tasks
Adding an LDAP user registry on Linux
Adding an LDAP user registry over SSL on Linux
Configuring a stand-alone LDAP user registry on Linux
Configuring a stand-alone LDAP user registry over SSL on Linux
Querying the defined attributes on Linux

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `./ConfigEngine.sh wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (PersonAccount) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on Linux in a clustered environment
Adding attributes on Linux in a clustered environment

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file: Table 1. Steps for installing the .ear file by environment

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone environment</td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the wp_profile_root/ConfigEngine directory. Run the ./ConfigEngine.sh wp-la-install-ear -DWasPassword=password task.</td>
</tr>
<tr>
<td>Clustered environment</td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the wp_profile_root/ConfigEngine directory on the primary node. Run the ./ConfigEngine.sh wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name task. Where node_name is the name of the node where the deployment manager resides; you can find the node_name value in the WebSphere Application Server Administrative Console under System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

3. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

4. Enter a value for the following required parameters in the wkplc.properties file under the VMM Property Extension Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - la.providerURL
   - la.propertyName
   - la.entityTypes
   - la.dataType
   - la.multiValued

5. Save your changes to the wkplc.properties file.
6. Run the `./ConfigEngine.sh wp-add-property -DWasPassword=password` task to add the attribute to the user registry.

   **Note:** This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

   **Remember:** If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents.*

   If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Adapting the attribute configuration

Mapping attributes on Linux in a clustered environment

After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs. Perform the following steps to map attributes between WebSphere Portal and your LDAP server; if you have multiple LDAP servers, you will need to perform these steps for each LDAP server:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Enter a value for one of the following sets of parameters in the wkplc.properties file to identify your LDAP server:
   
   **Note:** Make sure you use the same values you used to configure your LDAP server.

   *Table 1. Identifying your LDAP server in the wkplc.properties file.*

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:

   *Table 2. Task to check that all defined attributes are available in the configured LDAP user registry.*

4. Open the ConfigTrace.log file, located in the wp_profile_root/ConfigEngine/log directory, to review the following output for the PersonAccount and Group entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the uid, cn, firstName, sn, preferredLanguage, and ibm-primaryEmail attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

6. Enter a value for one of the following sets of parameters in the wkplc.properties file to correct any issues found in the config trace file: Table 3. Parameters to define in the wkplc.properties file to correct any issues found in the config trace file.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>The following parameters are found under the LDAP attribute configuration heading: <strong>Note:</strong> See the properties file for specific information about the required parameters and for advanced parameters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>

</tr>
</thead>
</table>
7. Save your changes to the \texttt{wkplc.properties} file.

8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

   \textbf{Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.}

   \begin{tabular}{|l|l|}
   \hline
   Repository type & Task \tabularnewline
   \hline
   Stand-alone & \texttt{./ConfigEngine.sh wp-update-standalone-ldap-attribute-config -DWasPassword=\text{password} task, from the \text{wp_profile_root}/ConfigEngine directory} \tabularnewline
   \hline
   Federated & \texttt{./ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=\text{password} task, from the \text{wp_profile_root}/ConfigEngine directory} \tabularnewline
   \hline
   \end{tabular}

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: \emph{Starting and stopping servers, deployment managers, and node agents}.

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:

   A. Enter a value for the following required parameters in the \texttt{wkplc.properties} file: \textbf{Note}: See the properties file for specific information about the required parameters and for advanced parameters.

      - \texttt{user.attributes.required}
      - \texttt{user.attributes.nonsupported}

   B. Save your changes to the \texttt{wkplc.properties} file.

   C. Run the \texttt{./ConfigEngine.sh wp-update-attribute-config -DWasPassword=\text{password} task, from the \text{wp_profile_root}/ConfigEngine directory}.

   D. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the \texttt{enable-jcr-security} task on the secondary node. See \emph{Enabling LDAP security after cluster creation} for instructions.

Enabling LDAP security after cluster creation
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database:

**Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.
   
   A. Open the tool you use to edit your database.
   
   B. Verify that your attribute name is available in the LAPROP table.
   
   C. Delete the required attributes from the LAPROP table.
   
   D. Open the `wimxmlextension.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/model` directory.
   
   E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```

   F. Save your changes to the `wimxmlextension.xml` file.

   G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/config` directory.

   H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:

   ```xml
   <config:propertiesNotSupported name="attribute_name"/>
   ```

   I. Save your changes to the `wimconfig.xml` file.

   J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:
   
   A. Open the `wimxmlextension.xml` file.
   
   B. Locate and delete the `propertySchema` definition for the attributes you previously added; for example:

   ```xml
   <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
   </wim:propertySchema>
   ```

   C. Save your changes to the `wimxmlextension.xml` file.

   D. Open the `wimconfig.xml` file.

   E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:

   ```xml
   <config:attributes name="attribute_name" propertyName="property_name">
     <config:entityTypes>PersonAccount</config:entityTypes>
   </config:attributes>
   ```

   F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

Parent topic: Adapting the attribute configuration
Previous topic: Mapping attributes on Linux in a clustered environment
Preparing additional nodes on Linux

After installing and configuring your primary node, you can create your secondary nodes. You must install IBM® WebSphere® Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

- Prerequisites
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux
  - Installing a secondary node after migrating from previous version

Perform the following tasks to prepare your secondary node:

- **Installing WebSphere Portal on Linux on the additional nodes**
  Install IBM WebSphere Portal on your secondary nodes to create a highly available and scalable environment.

- **Choosing the type of additional node to create on Linux**
  If you created a static cluster using the IBM WebSphere Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

- **Choosing the type of vertical cluster to create on Linux**
  If you are using the IBM WebSphere Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

**Parent topic:** Setting up a cluster on Linux

**Previous topic:** Configuring WebSphere Portal to use a user registry on Linux in a clustered environment

**Next topic:** Tune your servers
Installing WebSphere Portal on Linux on the additional nodes

Install IBM® WebSphere® Portal on your secondary nodes to create a highly available and scalable environment.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. **Note:** If you plan to use IBM WebSphere Application Server Version 7.0, you must purchase and install it before installing WebSphere Portal on the existing WebSphere Application Server Version 7.0 instance.

Perform the following steps to install WebSphere Portal:

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   - **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities

3. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:
   - **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   A. Install the current supported version of WebSphere Application Server as a root user.
   B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:

   1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
   2. Run the following tasks to change the rights of the non-root user:
      ```bash
      chmod -R g+rw /opt/IBM
      chgrp -R group_name /opt/IBM
      chmod -R g+wr /tmp
      chgrp -R group_name /tmp
      chmod -R g+wr /var/tmp
      ```
C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

4. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information: Advance installation parameters: To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

Restriction: When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graphical user interface</td>
<td>./install.sh</td>
</tr>
<tr>
<td>Console mode</td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td>Silent Install</td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. Important: Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

5. Verify your installation was successful; access WebSphere Portal using the http://yourserver:yourport/wps/portal format. Run the .ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

6. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

Note: The starting port parameter is required for a successful completion of the modify-ports-by-startport task. Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

A. Stop the server1 and WebSphere_Portal servers.
B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

7. Perform the following steps if you migrated from a previous version of WebSphere Portal:
   A. Log on to the WebSphere Application Server Administrative Console.
   C. Click WP Identification.
   D. Click Custom properties.
   E. If applicable, note the location of the LpidToGupidMapping.properties file.
   F. If the LpidToGupidMapping.properties file exists on the primary node, copy the file to the same location on the secondary node.

Choosing the type of additional node to create on Linux

If you created a static cluster using the IBM® WebSphere® Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

Choose one of the following options to add additional nodes to your cluster:

- **Adding additional nodes to the static cluster on Linux**
  After installing IBM WebSphere Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

- **Adding an additional node to an existing dynamic cluster**
  After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM WebSphere Virtual Enterprise dynamic cluster.

**Parent topic:** Preparing additional nodes on Linux
Adding additional nodes to the static cluster on Linux

After installing IBM® WebSphere® Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

Perform the following steps to add the secondary node to the cluster:

1. Perform the following steps on the secondary node to access your database server:
   - Note: All properties files are located in the `wp_profile_root/ConfigEngine/properties` directory.
   - For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes.
   - **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   - For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   - Set all database properties in the `wkplc_dbtype.properties` and `wkplc_comp.properties` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   - A. `./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password`
   - B. `./ConfigEngine.sh validate-database-connection -DWasPassword=password -DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory of the secondary node:
   - **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   - A. Verify that `WasUserid` is set to your deployment manager administrator ID.
   - B. Verify that `WasPassword` is set to your deployment manager administrator password.
   - C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   - D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   - E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   - F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is 8879.
   - G. Verify that `PrimaryNode` is set to `false`.
   - H. Verify that `ClusterName` is set to the primary node’s `ClusterName`.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
   - **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.
   - A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.
   - **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or property extension database, set the property value for `federated.db.DbType` or `la.DbType` as appropriate.
registry or a property extension database, set the property value for `federated.dbDbType` to the same value that is in the wkplc.properties file on the primary node.

6. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the wp_profile_root/ConfigEngine directory to create the variable used to access the VMM database jars.

   **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=dmgr_password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the wp_profile_root/ConfigEngine directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the wkplc.properties file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the wp-change-portal-admin-user task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the wp-change-portal-admin-user task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the wkplc.properties file if required.

8. Optional: Open the wkplc.properties file and change the `ServerName` parameter from the default WebSphere_Portal_nodename value to a value that meets your business needs. Do not change the parameter to WebSphere_Portal as this is the primary node value.

9. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task to add the node to your cluster.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Perform the following steps to access the Web Content Management content through an external Web server:

    A. Log on to the deployment manager administrative console.

    B. Select **Environment > WebSphere Variables**.

    C. From the **Scope** drop-down menu, select the `Node=node_name, Server=servername` option to narrow the scope of the listed variables, where `Node=node_name` is the node that contains the application server.
D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes.**
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize.**

G. Log off of the deployment manager administrative console.

12. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Choosing the type of additional node to create on Linux

**Related tasks**

Deleting passwords from properties files
Adding an additional node to an existing dynamic cluster

After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM® WebSphere® Virtual Enterprise dynamic cluster.

On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- Prerequisites
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
  - Augmenting profiles

Perform the following steps to add an additional node to an existing WebSphere Virtual Enterprise dynamic cluster:

1. Perform the following steps on the secondary node to access your database server: **Note:** All properties files are located in the wp_profile_root/ConfigEngine/properties directory.
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   C. Set all database properties in the wkplc_dbtype.properties and wkplc_comp.properties files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. ```/ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=```
   B. ```/ConfigEngine.sh validate-database-connection -DWasPassword= -DTransferDomainList=release,customization,community,jcr,feedback,likeminds```

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root\ConfigEngine\properties directory of the secondary node: **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   A. Verify that WasUserid is set to your deployment manager administrator ID.
   B. Verify that WasPassword is set to your deployment manager administrator password.
   C. Verify that PortalAdminId is set to your WebSphere Portal administrator ID.
   D. Verify that PortalAdminPwd is set to your WebSphere Portal password.
   E. Verify that WasRemoteHostName is set to the fully qualified host name of the deployment manager.
   F. Verify that WasSoapPort is set to the SOAP port that the deployment manager is using; the default value is 8879.
   G. Verify that PrimaryNode is set to false.
H. Verify that **ClusterName** is set to the primary node’s **ClusterName**.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

   **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

   A. Set the property value for **federated.db.DbType** if using a database user registry or set the property value for **la.DbType** if using a property extension database in the `wkplc.properties` file.

      **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for **federated.db.DbType** to the same value that is in the `wkplc.properties` file on the primary node.

   B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.

      **Note:** **VmmNodeName** is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The **db_type** in **db_type.NodeDbLibrary** should be set to the type of database you are using, for example **db2**.

6. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the **ServerName** parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the **newAdminId** and **newAdminGroupId** parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for **newAdminGroupId** contains a space; for example **Software Group**, open the `wkplc.properties` file and add the values for **newAdminId**, **newAdminPw**, and **newAdminGroupId**. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Log on to the deployment manager administrative console.

9. Perform the following steps to add members to the node group:

   A. Click **System administration > Node groups**.
B. Click on the name of the node group that you want to add members to.
C. Click **Node group members** under Additional Properties.
D. Click **Add**.
E. Select the additional node you want to add into the node group and then click **Add**.
F. Click the **Save** link to save your changes to the master configuration.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Define or verify the following parameters in the `wkplc.properties` file, located in the `wp_profile_root` directory:
   A. Set **ClusterName** to the name of the existing dynamic cluster.
   B. Verify that **CellName** is set to the deployment manager cell.
   C. Verify that **NodeName** is set to the local WebSphere Portal node.
   D. Set **ServerName** to the server that will be used for the dynamic cluster member on this node. **Note:** Log on to the deployment manager administrative console and click **Dynamic Clusters > PortalCluster > Dynamic cluster members** to find the name of the server used for the dynamic cluster.
   E. Verify that **PrimaryNode** is set to false because this is an additional node.

12. Run the `./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password` task to add the new member to the existing dynamic cluster. **Note:** This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

13. Perform the following steps to start the cluster member:
   A. Log on to the Deployment Manager administrative console.
   B. Navigate to **Servers > Dynamic clusters > cluster name > Dynamic cluster members**.
   C. Select the cluster member and click **Start**.
   D. Log off of the deployment manager administrative console.

14. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select **Environment > WebSphere Variables**.
   C. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server.
   D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select **System Administration > Nodes**.
      2. Select the node that you want to synchronize from the list.
      3. Click **Full Resynchronize**.
   G. Log off of the deployment manager administrative console.

15. Run the following tasks to propagate your changes: **Note:** `WebSphere_Portal_nodename` is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the `serverstatus -all` task to get a list of the server names and their status.
   A. `./stopManager.sh -username admin_userid -password admin_password`, from the `dmgr_profile_root\bin` directory
   B. `./stopNode.sh -username admin_userid -password admin_password`, from the `wp_profile_root\bin` directory
   C. `./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`
D. ./startManager.sh, from the dmgr_profile_root\bin directory
E. ./startNode.sh, from the wp_profile_root/bin directory
F. ./startServer.sh WebSphere_Portal_nodename

16. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

Parent topic: Choosing the type of additional node to create on Linux

Choosing the type of vertical cluster to create on Linux

If you are using the IBM® WebSphere® Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

Choose one of the following options to add vertical cluster members to your cluster.

- **Adding vertical cluster members to a static cluster on Linux**
  
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

- **Adding vertical cluster members to a dynamic cluster on Linux**
  
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Parent topic: Preparing additional nodes on Linux
Adding vertical cluster members to a static cluster on Linux

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Log into the deployment manager administrative console.
2. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - For WebSphere Application Server Version 6.1: Click Servers > Clusters in the console navigation tree, select the cluster name, and then click Cluster members from the list of additional properties.
   - For WebSphere Application Server Version 7.0: Click Servers > Clusters > WebSphere application server clusters > cluster_name > Cluster members.
   - Click New to create the cluster member.
     - Define the name of cluster member. Note: Do not use spaces in the cluster member name.
     - Select an existing node where IBM® WebSphere® Portal is installed.
     - Check the box Generate Unique HTTP Ports.
     - Click Add Member and then click Next to view the summary.
     - Important: You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.
     - Click Finish, and save the changes.
3. The new cluster topology can be viewed from the Servers > Cluster Topology view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the Servers > Clusters > Cluster Topology view.
4. Perform the following steps to enable cache replication:
   - From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new vertical cluster member(s).
   - Click Dynamic cache service under Container services.
   - Change Cache size to 3000 entries.
   - Check the Enable cache replication check box.
   - Select NOT_SHARED from the Replication type drop-down menu.
   - Click OK.
   - Click Save to save your changes to the master configuration.
5. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   - Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   - Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.
7. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Resynchronize.
   G. Log off of the deployment manager administrative console.

8. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click Save on the task bar, and save your administrative configuration.
   B. Select System Administration > Nodes, select the node from the list, and click Full Resynchronize.

9. Regenerate the Web server plug-in.
   A. Regenerate the Web server plug-in using the deployment manager administrative console.
   B. If you are using a remote Web server, copy the updated plug-in configuration file (plugin-cfg.xml) to the Web server's plug-in configuration directory.

10. Stop and start the Web server.

Parent topic: Choosing the type of vertical cluster to create on Linux
Adding vertical cluster members to a dynamic cluster on Linux

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Open a browser and enter `http://DM01:9060/ibm/console` in the address bar to access the administrative console on the deployment manager, where `DM01` is the deployment manager node or host name. The port number might differ based on your installation.

2. Perform the following steps to allow vertical clusters on your dynamic cluster:
   A. Navigate to `Servers > Dynamic clusters` and select the appropriate dynamic cluster.
   B. Select the **Allow more than one instance to start on the same node** check box under **Vertical stacking of instances on node**.
   C. Enter a new value in the **Number of instances** text box to determine the number of vertical cluster members allowed on each node.
   D. Click **Apply** and then click **Save** to save the changes to the master configuration.

3. Perform the following steps to enable cache replication:
   A. From the deployment manager Administrative Console, navigate to `Servers > Application servers` and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to `Servers > Server Types > WebSphere application servers` and then click the new vertical cluster member(s).
   B. Click **Dynamic cache service** under **Container services**.
   C. Change **Cache size** to 3000 entries.
   D. Check the **Enable cache replication** check box.
   E. Select **NOT_SHARED** from the **Replication type** drop-down menu.
   F. Click **OK**.
   G. Click **Save** to save your changes to the master configuration.

4. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   A. Run the `./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, where `unique vertical cluster servername` is the name you specified when you created the cluster member.
   B. Restart the vertical cluster member referenced in the **cluster-node-config-vertical-cluster-setup** task.

5. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
B. Select **Environment > WebSphere Variables**.

C. From the **Scope** drop-down menu, select the `Node=nodename, Server=servername` option to narrow the scope of the listed variables, where `nodename` is the node that contains the application server.

D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

6. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click **Save** on the task bar, and save your administrative configuration.
   B. Select **System Administration > Nodes**, select the node from the list, and click **Full Resynchronize**.

7. Stop and start the Web server.

**Parent topic:** Choosing the type of vertical cluster to create on Linux
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- Prerequisites
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux
  - Base Portal Tuning Scenarios

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services

Parent topic: Setting up a cluster on Linux

Configuring search in a cluster on Linux

IBM® WebSphere® Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux
  - Tune your servers

- **Configuring Portal Search in a cluster on Linux**
  To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM WebSphere Application Server node that is not part of the IBM WebSphere Portal cluster.

- **Configuring JCR search in a cluster on Linux**
  To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

Parent topic: Setting up a cluster on Linux

Previous topic: Tune your servers

Next topic: Setting up multiple clusters on Linux
Configuring Portal Search in a cluster on Linux

To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM® WebSphere® Application Server node that is not part of the IBM WebSphere Portal cluster.

To install and configure the search service remotely, perform the following tasks:

1. Install and configure the search service to work remotely, that is, on a remote WebSphere Application Server node which is not part of the portal cluster. You can provide the remote search service either as an EJB or as a Web service via SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server node. For details about how to do this, refer to the WebSphere Application Server documentation.
2. Configure the search portlets for remote search service so that they access the remote server accordingly.

Notes:
1. If you have configured a remote search service for a portal cluster, you need to configure the default location for search collections to a directory on the remote server that has write access.
2. The portal site default search collection is created only once at the first time when an administrator selects the search administration portlet Manage Search. If this occurred before you configure the portlet for remote search, then the default portal site search collection is only available on the primary node of the cluster, but not on the remote server. In this case you need to recreate the portal site collection to make it available for search on all nodes of the cluster.

Parent topic: Configuring search in a cluster on Linux

Related concepts
Planning and preparing for Portal Search
Using remote search service

Related tasks
Configuring Portal Search for remote search service
Configuring the Search and Browse portlet for remote search service
Configuring the default location for search collections
Creating or resetting the portal site collection
Configuring the primary node to communicate with the deployment manager on Linux
Configuring a remote search service
Configuring JCR search in a cluster on Linux

To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization. Create a shared directory called `jcr/search` on a server in the network and ensure that each node in the cluster and the Deployment Manager has network access to the directory.

**Note:** If you are creating content in a clustered environment using the authoring portlet provided with Web Content Management, additional configuration steps are required to enable content created by these content features to be searchable in a cluster.

Perform the following steps on each server in the cluster to configure Search in a clustered environment:

1. Edit the `icm.properties` file, located in the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory.
2. Change the value of the `jcr.textsearch.indexdirectory` property to the shared directory; for example, `jcr.textsearch.indexdirectory=\\your_server\your_share\jcr\search`. You can specify the shared directory value in one of the following formats: **Table 1. The format for the shared directory.**

<table>
<thead>
<tr>
<th>Format</th>
<th>Shared directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal Naming Convention (UNC)</td>
<td><code>\\\your_server\your_share\jcr\search</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>\\\hostname.example.com\share\jcr\search</code></td>
</tr>
<tr>
<td>Mounted resource format (with forward slashes)</td>
<td><code>/your_share/jcr/search</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>/mnt/jcr/search</code></td>
</tr>
<tr>
<td><strong>Important:</strong> This format requires that you mount the shared directory to the local server (for example, through a mapped network drive or a mounted directory). When using the mounted resource format, always use forward slashes instead of back slashes, regardless of the native operating system path format.</td>
<td></td>
</tr>
</tbody>
</table>

3. Required: Perform the following steps to delete the default search collections from the Manage Search portlet:

   A. Log on to WebSphere Portal as an administrator.
   B. Click **Administration > Search Administration > Manage Search**.
   C. Click **Search Collections**.
   D. Click the **Delete Collection** icon for the **Portal Content** search collection.
   E. Click **OK**.
   F. Restart the WebSphere_Portal server.
   G. Go to the Manage Search portlet and confirm that the **Portal Content** search collection was deleted.

**Parent topic:** Configuring search in a cluster on Linux
Setting up multiple clusters on Linux

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM® WebSphere® Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

Before attempting alternative approaches for building multiple portal-based clusters within a single cell, please contact IBM.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux
  - Tune your servers

- **Installing multiple clusters in a single cell on Linux**
  Create a new, independent IBM WebSphere Portal cluster in a cell where a WebSphere Portal cluster already exists.

- **Routing requests across clusters on Linux**
  The HTTP Server plug-in that comes with IBM WebSphere Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

**Parent topic:** Setting up a cluster on Linux

**Previous topic:** Configuring search in a cluster on Linux

**Next topic:** Sharing database domains between clusters on Linux
Installing multiple clusters in a single cell on Linux

Create a new, independent IBM® WebSphere® Portal cluster in a cell where a WebSphere Portal cluster already exists. In the following steps, Cluster A will be used to describe the existing cluster. Portal B will be used to describe the new server profile that will be the basis for the new cluster definition, Cluster B. Perform the following steps to install multiple clusters in a single cell:

1. Upgrade Cluster A, including the Deployment Manager node, to the current, supported hardware and software levels and to the current version of IBM WebSphere Portal.
2. Install and configure Portal B; see the "Preparing the primary node" topic for the appropriate operating system for details. Important: Maintain the same number of data sources with identical names to the Cluster A data sources so that data source bindings in the applications can be resolved on every cluster in which they run. If implementing database sharing across the clusters, the above statement refers to both the shared and non-shared domains; all domains should use the same names.
3. Optional: Using the same database user ID and password for each identically named domain/data source will allow the existing JAAS Authentication Aliases to be functional. If unique database user ID and password are required, additional manual configuration is needed to create new JAAS Authentication Aliases for each data source and map these accordingly. On the primary node of Cluster A, run the ./ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the new JAAS Authentication Aliases. Where authDomainList is set to a list of domains which use unique database user ID and passwords and those domain properties are set correctly in the wkplc_comp.properties file, including user ID and password.
4. Optional: If necessary, upgrade Portal B to the current cumulative fix.
5. Run the ./ConfigEngine.sh mapped-app-list-create -DWasPassword=password /ConfigEngine directory to build an inventory list of Portal B enterprise applications and portlets.
6. Stop the server1 and WebSphere_Portal servers on Portal B and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   - Set WasSoapPort to the deployment manager's port.
   - Set WasRemoteHostName to the full host name of the deployment manager.
7. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading. Important: Ensure that you set WasUserId and WasPassword to the Deployment Manager user ID and password.
8. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=password task, from the wp_profile_root/ConfigEngine of the primary node.
9. Run the ./ConfigEngine.sh map-apps-to-server -DWasPassword=password task to determine which applications from the inventory list are no longer mapped to Portal B. The task uses the application profiles already in the cell to restore the mappings. Wait 30 minutes after running this task to allow all EAR files to expand before proceeding to the next step.
10. Perform the following steps to federate Portal B into the deployment manager cell:
   A. Ensure that all database parameters are correctly set, including passwords, in the wkplc_comp.properties and wkplc_dbtype.properties files.
B. Run the \\ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password\ task.

C. After running the cluster-node-config-post-federation\ task, wait at least 30 minutes to allow all EAR files to expand.

D. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the \\ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=\password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid\ task, from the wp_profile_root/ConfigEngine directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.

Important: If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the wp-change-portal-admin-user\ task until after the cluster-node-config-cluster-setup (static cluster) or cluster-node-config-dynamic-cluster-setup (dynamic cluster) task completes. After running the wp-change-portal-admin-user\ task, start or restart the WebSphere Portal server to use the updated administrator user ID.

Note: The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the wp-change-portal-admin-user\ task. -DnewAdminPw is an optional parameter to update the Administrative password in the wkplc.properties file if required.

E. From the administrative console, click System Administration > Node Agents.

F. Check the box next to the required node agent and then click Restart.

G. Stop and restart the deployment manager.

H. Stop and restart the WebSphere Portal server on Portal B

11. Restart the WebSphere Portal server on Cluster A. Verify that Cluster A is functionally intact by spot checking pages and portlets and then verify that Portal B is functionally intact by spot checking pages and portlets that you deployed into Portal B before it was federated. Any discrepancies or errors should be corrected now before continuing. Note: If Portal B is using a non-default Portal server administrative ID, not wpsadmin, the server will not be functional until the cluster configuration is complete and the Portal administrative ID has been configured to match the Cells security settings.

12. Choose one of the following options to define a cluster using Portal B as the basis:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>

1778
Perform the following steps to define a static cluster using **Portal B** as the basis: Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password` task. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:

- Configuring a Web server and an application server on separate machines (remote)
- Configuring a Web server and an application server profile on the same machine
- Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard. Perform the following steps to access the Web Content Management content through an external Web server: Log on to the deployment manager administrative console. Select **Environment > WebSphere Variables**. From the **Scope** drop-down menu, select the `Node=nodename, Server=servername` option to narrow the scope of the listed variables, where `Node=nodename` is the node that contains the application server. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere_Portal servers. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

- Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
- Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Dynamic cluster

Perform the following steps to define a dynamic cluster using **Portal B** as the basis:

1. Log on to the deployment manager administrative console.
2. Perform the following steps to create a node group:
   - Click **New**. Type the node group **Name**. Type any information about the node group in the **Description** text box. Click **OK**. Click the **Save** link to save your changes to the master configuration.
3. Perform the following steps to add members to the node group:
   - Click **System administration > Node groups**. Click on the name of the node group that you want to add members to. Click **Node group members** under **Additional Properties**. Click **Add**. Select the primary node and then click **Add**. Click the **Save** link to save your changes to the master configuration.
4. Perform the following steps to create a dynamic cluster in the node group:
   - Click **Servers > Dynamic clusters**. Click **New**. Select WebSphere Application Server from the **Server Type** pull-down menu and then click **Next**. Type the cluster name in the **Dynamic cluster name** text box and then click **Next**. Type the same value that you provided for the **ClusterName** parameter in the `wkplc.properties` file of your primary node.
   - Remove all default membership policies and then click **Subexpression builder**. Enter the following information in the Subexpression builder window:
     - Select **Logical operator** pull-down menu. Select **Nodegroup** from the **Select operand** pull-down menu. Select **Equals (=)** from the **Operator** pull-down menu. Type the nodegroup name you created in the previous step in the **Value** text box. Click **Generate subexpression**. Click **Append**. Click **Preview membership** to verify that all nodes included in the nodegroup display and then click **Next**. Click **Create the cluster member using an existing server as a template** radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu.
   - Click **Next**. Specify the dynamic cluster properties and then click **Next**.
   - Review the summary page to verify your actions and then click **Finish**.
5. Define or verify the following parameters in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory:
   - Set **ClusterName** to the name of the new dynamic cluster.
   - Verify that **CellName** is set to the deployment manager cell.
   - Verify that **NodeName** is set to the local WebSphere Portal node.
   - Set **ServerName** to the server that will be used for the dynamic cluster member on this node.
   - Verify that **PrimaryNode** is set to true.
6. Run the `./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password` task from the `wp_profile_root/ConfigEngine` directory to create the dynamic...
13. Install any additional nodes to the cell to support additional cluster members for Cluster B identically to the primary node, and then federate as them as secondary nodes and define as cluster members on these nodes. For information about adding additional nodes navigate to Installing WebSphere Portal > Setting up WebSphere Portal > Setting up a clustered production environment. Select Environment > WebSphere Variables. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere Portal servers. If you are using a Web server to connect to the On Demand Router (ODR), configure the web server as a trusted proxy on the ODR. Refer to Configuring a Web server as a trusted proxy server for instructions. Tip: You can also configure the ODR to dynamically update the Web server configuration when changes occur. Refer to Configuring an on demand router to dynamically update the Web server plug-in configuration for instructions.

Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information: Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup

14. Restart the server1 and WebSphere_Portal servers on Cluster A and Cluster B.

15. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See “Deleting passwords from properties files” under Related tasks for information.

Installation of Cluster B is complete. It is now an independent cluster from Cluster A, which means that Cluster B can have its own configuration, set of end-user portlets, and target community. Any applications that are common between Cluster A and Cluster B are most likely infrastructure or related to administration, and special care needs to be taken to preserve their commonality between clusters and correct maintenance levels.

Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Routing requests across clusters on Linux

The HTTP Server plug-in that comes with IBM® WebSphere® Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

An important consideration in a multiple cluster environment is ensuring that all subsequent HTTP requests for an end user are routed to the same cluster that processed the first HTTP request. The WebSphere Portal login processing depends upon preserving this cluster affinity during this initial time until the user has successfully logged in and session cookies maintain affinity. In order to guarantee that affinity is preserved during login, set the Navigator Service public.session parameter to a value of true. Refer to “Portal Configuration Services” for information on how to configure this parameter.

Parent topic: Setting up multiple clusters on Linux
Sharing database domains between clusters on Linux

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM® WebSphere® Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Linux
  - Preparing your Linux operating system
  - Preparing the primary node on Linux
  - Tune your servers

**Important:** JCR domains and release domains cannot be shared between different Web Content Management clusters or servers. Each distinct cluster or server in your Web Content Management system must use a separate JCR or release domain. For example:

<table>
<thead>
<tr>
<th>Development Server</th>
<th>Authoring Cluster</th>
<th>Staging Server</th>
<th>Delivery Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>JCR Domain 1</td>
<td>JCR Domain 2</td>
<td>JCR Domain 3</td>
<td>JCR Domain 4</td>
</tr>
<tr>
<td>Release Domain 1</td>
<td>Release Domain 2</td>
<td>Release Domain 3</td>
<td>Release Domain 4</td>
</tr>
</tbody>
</table>

Perform the following steps to share database domains when setting up an environment with multiple clusters:

1. Set up the first cluster (referred to as Cluster A in these instructions).
2. Determine which database domains you want to share with any other clusters in the environment.
3. Install the primary node of the next cluster (Cluster B), and perform the following steps to configure the node to use the shared database domains.
   A. Perform a partial database transfer of the database domains that you are not sharing. For example, if you are sharing only the Customization and Community domains, you would transfer the remaining domains to the database you are using for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.
4. Continue setting up the primary node as described in the cluster instructions.
5. Install the secondary node of Cluster B, and perform the following steps to configure the node to use the shared database domains.
   A. For those database domains that you are not sharing between clusters, reconfigure the domains to connect to the database domains you are using for Cluster B. As in the example for the primary node, if you are sharing only the Customization and Community domains, reconfigure the remaining domains on the secondary node to use the domains of the primary node for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to...
those domains from Cluster B.

6. Continue setting up the secondary node as described in the cluster instructions.

**Related tasks**  
Connecting to existing database domains
Setting up a cluster on Solaris

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- **Prerequisites**
  - [Technotes for installation and configuration issues](#)

Perform the following steps to set up your production environment on Solaris:

1. **Preparing prerequisite and corequisite software on Solaris**
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your Solaris operating system**
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on Solaris**
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Choosing the type of cluster to create on Solaris**
   If you installed a IBM WebSphere Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

5. **Preparing a remote Web server when portal is installed on Solaris**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment**
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

7. **Preparing additional nodes on Solaris**
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

8. **Tune your servers**
   Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

9. **Configuring search in a cluster on Solaris**
   IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.
10. **Setting up multiple clusters on Solaris**

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

11. **Sharing database domains between clusters on Solaris**

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

Preparing prerequisite and corequisite software on Solaris

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. **Preparing the WebSphere Application Server Deployment Manager on Solaris**
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. **Preparing a remote Web server when portal is installed on Solaris**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

**Parent topic:** Setting up a cluster on Solaris

**Next topic:** Preparing your Solaris operating system
Preparing the WebSphere Application Server Deployment Manager on Solaris

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command: cd_root/Solaris/architecture/ifpackage/NAS/install, where cd_root is the root directory of the disc and architecture is the system's processor architecture.

2. Choose one of the following options to create a default deployment manager profile: Important: While creating the default deployment manager profile, enable administrative security. If you use the Profile Management Tool, check the enable administrative security check box. If you use the manageprofile command, add the -enableAdminSecurity=true parameter to the command line.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile Management Tool</td>
<td>See Creating a deployment manager profile for information.</td>
</tr>
<tr>
<td>manageprofile commands</td>
<td>See manageprofile commands for information. Note: If you have a 64-bit environment, only the manageprofiles command is supported when creating profiles.</td>
</tr>
</tbody>
</table>

3. Run the following command to start the deployment manager: ./startManager.sh, from the dmgr_profile_root/bin directory.

4. Use the following URL to launch the network deployment administrative console: http://dmgr_hostname:9060/ibm/console, where dmgr_hostname is the fully qualified host name for the WebSphere Application Server Network Deployment.

5. Log into the deployment manager administrative console.

6. Increase the HTTP connection timeouts for the deployment manager:

   A. Click System Administration > Deployment Manager > Web container transport chains.
   
   B. Increase the timeout values. For the WCInboundAdmin and WCInboundAdminSecure entries listed in the web container transport chains section, complete the following steps to increase the timeout values:

      1. Click HTTP Inbound Channel.
      2. Change the Read timeout value to 180.
      3. Change the Write timeout value to 180.
      4. Save the configuration changes.

7. Change the timeout request period for the Java Management Extensions (JMX) connector.

   A. Click System administration > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties.
   
   B. Select the requestTimeout property, and increase the value from 600 to 6000.
   
   C. Save the configuration changes.

8. Update the maximum Java heap size used by the deployment manager:

B. Update the value in the **Maximum Heap Size** field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management Product Documentation page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.

C. Click **OK** and then save your changes.

9. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - **Note:** If security is not enabled on your deployment manager, see **Enabling security** for information before performing this step.
     - For **WebSphere Application Server Version 6.1**: Click **Security > Secure administration, applications and infrastructure** and select **Enable Application Security**. Then save the configuration changes.
     - For **WebSphere Application Server Version 7.0**: Click **Security > Global security** and select **Enable Application Security**. Then save the configuration changes.

10. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:
   A. Click **Users and Groups > Manage Users**.
   B. Click **Create**.
   C. Type the information for the WebSphere Portal administrative users; for example **wpsadmin** and **wpsbind**, and then click **Create**.
   D. Click **Users and Groups > Manage Groups**.
   E. Click **Create**.
   F. Type **wpsadmins** as the name of the WebSphere Portal administrative group and then click **Create**.
   G. Click the group you just created; for example **wpsadmins**.
   H. Click the **Members** tab.
   I. Click **Add Users**.
   J. Search for the users.
   K. Select the users you want to add to the group.
   L. Click **Add** to add the users to the group.
   M. Click **Close** when you are done adding users to the group.
   N. Log out of the administrative console.

11. Change the timeout request period for the Simple Object Access Protocol (SOAP) client. Edit the **soap.client.props** file, located in the Dmgr_profile/properties directory: Change the line to: **com.ibm.SOAP.requestTimeout=6000**.

12. Run the following tasks to stop and restart the deployment manager:
   A. **./stopManager.sh -username admin_userid -password admin_password**, from the dmgr_profile_root\bin directory
   B. **./startManager.sh**, from the dmgr_profile_root\bin directory

**Parent topic:** Preparing prerequisite and corequisite software on Solaris

**Next topic:** Preparing a remote Web server when portal is installed on Solaris
Preparing a remote Web server when portal is installed on Solaris

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

**Prerequisites**
- Preparing the WebSphere Application Server Deployment Manager on Solaris
- Preparing prerequisite and corequisite software on Solaris
- Preparing your Solaris operating system
- Preparing the primary node on Solaris

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the **NOTES.INI** file on the Web server. Set the **HTTPEnableConnectorHeaders** parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the **httpd.conf** file on the Web server. Set the **AllowEncodedSlashes** directive to **On**; the directive should be added at the root level as a global directive.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>See the appropriate HTTP Server</td>
<td>IBM HTTP Server</td>
</tr>
<tr>
<td>documentation</td>
<td></td>
</tr>
<tr>
<td>See the appropriate Apache Server</td>
<td>AllowEncodedSlashes</td>
</tr>
<tr>
<td>documentation</td>
<td>directives</td>
</tr>
</tbody>
</table>

4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to [Selecting a Web server topology diagram and roadmap](#) for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to [Configuring a Web server for a non-default profile](#).

   If using WebDAV: After successfully installing the Web server plug-in, locate and open your **plugin-cfg.xml** file and set **AcceptAllContent** to **true**.

   **Important:** Depending on how you use the Web server, you may need to adjust the **ServerIOTimeout** value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your **plugin-cfg.xml** file and set **ServerIOTimeout** to a value that is appropriate for your business needs. For additional information, see [Common questions about the Web server plug-in](#).

6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.
Preparing your Solaris operating system

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris

Perform the following steps to prepare your operating system:

1. Perform the following steps to prepare your Solaris kernel settings: Several Solaris kernel values are typically too small for the messaging requirements of WebSphere Portal. Starting the internal JMS server or client with insufficient kernel resources produces a First Failure Support Technology (FFST) file in the /var/errors directory. Before installing WebSphere Portal, review the machine's configuration.

   **Note:** The values described here are a starting point for messaging in WebSphere Portal only. If your system has other applications installed, the value requirements will likely be different. For example, if values that are already set are higher than the settings listed here, the values should not be lowered. Be sure to check the requirements made on /etc/system by other already-installed applications before altering existing values.

   A. Type the `sysdef -i` command to review the configuration.
   
   B. Set `shmsys:shminfo_shmmax` (valid for Solaris Version 9 only) to **4294967295**.
   
   C. Set `shmsys:shminfo_shmni` (valid for Solaris Version 9 only) to **1024**.
   
   D. Set `semsys:seminfo_semaem` (valid for Solaris Version 9 only) to **16384**.
   
   E. Set `semsys:seminfo_semni` (valid for Solaris Version 9 only) to **1024**.
   
   F. Set `semsys:seminfo_semmns` (valid for Solaris Version 9 only) to **16384**.
   
   G. Set `semsys:seminfo_semmsl` (valid for Solaris Version 9 only) to **100**.
   
   H. Set `semsys:seminfo_semmopm` (valid for Solaris Version 9 only) to **100**.
   
   I. Set `semsys:seminfo_semmnu` (valid for Solaris Version 9 only) to **2048**.
   
   J. Set `semsys:seminfo_semmue` (valid for Solaris Version 9 only) to **256**.
   
   K. Set `msgsys:msginfo_msgmap` (valid for Solaris Version 9 only) to **1024**.
   
   L. Set `msgsys:msginfo_msgmax` (valid for Solaris Version 9 only) to **65535**.
   
   M. Set `rlim_fd_cur` to **1024**.

2. **Web Content Management only:** Use the `ulimit -f` command to set the maximum size of files that can be created to be at least the size of the largest file you would need to upload to the content server. The command `ulimit -f -1` removes any limit on file size.

3. Set the file descriptor limit to **10240**; for example, `ulimit -n 10240`.

4. Perform the following steps to prepare for non-global zone:

   A. Do not inherit package directories when you create the non-global zone because the inherited software packages will be read-only.

   B. Stop WebSphere Portal and all related processes before installing or uninstalling.

   C. Verify that the following processes are stopped:

      - `/opt/IBM/WebSphere/AppServer/java/bin/java`
      - `/opt/IBM/WebSphere/AppServer/java/jre/bin/java`

---

**Parent topic:** Setting up a cluster on Solaris

**Previous topic:** Preparing prerequisite and corequisite software on Solaris
Next topic: Preparing the primary node on Solaris
Preparing the primary node on Solaris

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system

Perform the following tasks to prepare your primary node:

1. **Installing WebSphere Portal on Solaris on the primary node**
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. **Configure WebSphere Portal to use a remote database**
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

3. **Configuring the primary node to communicate with the deployment manager on Solaris**
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. **Removing search collections on Solaris**
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Parent topic:** Setting up a cluster on Solaris

**Previous topic:** Preparing your Solaris operating system

**Next topic:** Choosing the type of cluster to create on Solaris
Installing WebSphere Portal on Solaris on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method.

Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - Application Server
   - Administration
   - Scripted Administration
   - Administrative Console
   - Ant and Deployment Tools
   - Deploy Tool
   - Ant Utilities
   **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.
   **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

4. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:
   **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.
   A. Install the current supported version of WebSphere Application Server as a root user.
   B. Open a command prompt and perform the following steps to create a non-root user and to change ownership:

   1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
      
      ```
      chgrp -R group_name/opt/IBM
      chmod -R g+rw /opt/IBM
      chmod -R g+wr /tmp
      ```
   2. Run the following tasks to change the rights of the non-root user:

      ```
      chgrp -R group_name/opt/IBM
      chmod -R g+rw /opt/IBM
      chmod -R g+wr /tmp
      ```
chgrp -R group_name /tmp
chmod -R g+wr /var/tmp
chgrp -R group_name /var/tmp

C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:

**Advance Installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

**Restriction:** When defining your installation path, the **ONLY** supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

**Table 1. Installation task options**

<table>
<thead>
<tr>
<th>Installation type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graphical user interface</td>
<td>./install.sh</td>
</tr>
<tr>
<td>Console mode</td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td>Silent install</td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. <strong>Important:</strong> Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

**Important:** If you have a Solaris 9 on Sun SPARC, you MUST either add the -W defaults.force32bit=true parameter to your installation command or install the 32-bit WebSphere Application Server product before installing WebSphere Portal to prevent the installer from automatically selecting a 64-bit environment.

**Note:** If the installation program does not detect a WebSphere Application Server instance that you know exists, exit the installation program and pass the WebSphere Application Server instance location using the command line; for example, ./install.sh -W was.undetectedWas="/my/WAS/location".

**Note:** If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

6. Verify your installation was successful; access WebSphere Portal using the [http://yourserver:yourport/wps/portal format](http://yourserver:yourport/wps/portal). Run the ./ConfigEngine.sh list-server-ports -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to generate the wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt file that lists WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the ./ConfigEngine.sh configure-express -DPortalAdminPwD=password -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

**Restriction:** Run the configure-express task before configuring your database, user registry, context root, security, etc. If you ran any tasks other than the install task, do not run this task.

**Note:** See [http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html](http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html)
for tutorials on how to use the sample content.

The sample content includes:

- Creates a group called contentAuthors; members of this group are given privileges to create content in the sample Internet and intranet sites. Navigate to the **Administration** area and then click **Access > Users and Groups**.
- Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0". Navigate to the **Administration** area and then click **Portal Content > Web Content Libraries**.
- Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the **Environment** area.
- Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to **Theme Customizer** and then select the style.
- Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.
- Creates two virtual portals with context roots of wps/portal/intranet and wps/portal/internet. These are the sample Internet and intranet sites. Go to http://yourserver:yourport/wps/portal/internet and http://yourserver:yourport/wps/portal/intranet to access them.
- Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the **Administration** area and then click **Access > Credential Vault > Manage System Vault Slots**.
- Modifies the portlet palette to include some new portlets. Click the **Portlets** link to see the portlet palette.

8. Optional: If you ran the configure-express task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as uid=xyzadmin,o=defaultWIMFileBasedRealm. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:

A. Edit the wp_profile_root
   /PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following line to the file:
   ```
   uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN
   ```
   Replace `portal_admin_DN` with the distinguished name of the portal administrator.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory.

9. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

   **Note:** The starting port parameter is required for a successful completion of the modify-ports-by-startport task. Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

A. Stop the server1 and WebSphere_Portal servers.
B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=start_port_number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

10. To prevent Out of Memory errors, perform the following steps to set the MaxPermSize:

Tip: If Maximum Heap Size is set to 2048 M or higher, set the MaxPermSize to a quarter of the value entered for the Maximum Heap Size; for example, if your Maximum Heap Size is 3000 M, set MaxPermSize to 750 M. If your Maximum Heap Size is less than 2048 M, set MaxPermSize to 512 M.

A. Log in to the WebSphere Application Server Administration Console.

B. Click Servers > Server Types > WebSphere application servers > WebSphere_Portal.

D. In the Generic JVM arguments field, change the MaxPermSize value to -XX:MaxPermSize=numeric value, where numeric value is a quarter of the value entered for the Maximum Heap Size. Important: If MaxPermSize does not exist in the Generic JVM arguments field, add it to the field but do not replace existing information in the Generic JVM arguments field with the MaxPermSize information.

E. Click OK to save your changes.

F. Click Save to save your changes to the master configuration.

G. Log out of the WebSphere Application Server Administration Console.

H. Restart the server1 and WebSphere_Portal servers.

Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

Password considerations when transferring data manually

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts. Alternatively, you can specify the password on the command line using the following syntax:

- Windows: ConfigEngine.bat task_name -Dpassword_property_key=password_value
- UNIX: ./ConfigEngine.sh task_name -Dpassword_property_key=password_value
- i5/OS: ConfigEngine.sh task_name -Dpassword_property_key=password_value

As with other properties, each password property must have the -D prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each -Dproperty=value setting.

- Prerequisites
  - Installing WebSphere Portal on Solaris on the primary node
  - Technotes for database connectivity issues

- Configuring WebSphere Portal to use DB2
  View information on installing and setting up DB2 to work with WebSphere Portal.

- Configuring WebSphere Portal to use DB2 for z/OS
  View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle
  View information on installing and setting up Oracle to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle RAC
  View information on installing and setting up Oracle RAC to work with WebSphere Portal.

- Configuring WebSphere Portal to use SQL Server
  View information on installing and setting up SQL Server to work with WebSphere Portal.

- Verifying databases
  After you configure IBM WebSphere Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

Related Information
Configuring WebSphere Portal to use DB2

View information on installing and setting up DB2 to work with WebSphere Portal.

1. **Installing DB2**
   View information on installing DB2 for use with WebSphere Portal.

2. **Create users**
   View the steps to set up users for DB2 to work with WebSphere Portal.

3. **Creating remote databases**
   A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

4. **Optional: Assigning custom table spaces**
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

5. **Modifying database properties**
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

6. **Optional: Configuring JCR collation support**
   View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

7. **Configure WebSphere Portal to use DB2**
   View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

8. **Configuring DB2 for large file handling in Web Content Management**
   If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

9. **Optional: Changing driver types**
   WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing DB2

View information on installing DB2 for use with WebSphere Portal.

Before you begin:

- Make sure DB2 is set up with updated kernel parameters according to the recommendations in the DB2 Quick Beginnings guide at DB2 Technical Support.

- **(For Type 2 drivers only):** DB2 Connect must be installed on the same system as WebSphere Portal, and have the same name as the server profile name.

- When you install DB2 using the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.

1. If you are using the JDBC driver in type 2 mode, configure your DB2 Connect client with the following commands. If you are using a remote database, complete this step separately from the WebSphere Portal installation.
   - `db2 update dbm cfg using tp_mon_name WAS`
   - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name of WebSphere Portal.

   Because the default for `spm_name` is the hostname itself, specifying the `hostname` parameter is optional. If your hostname is more than eight characters, use empty double quotes (" "). For example, `db2 update dbm cfg using spm_name " "`.

2. Before installing DB2, log in with a user ID that has administrative authority.

3. To install DB2, follow the instructions that are provided with the DB2 documentation to install DB2 and the required fix pack.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Next topic:** Create users

**Related Information**

- DB2 Technical Support
- DB2 Information Center
Create users

View the steps to set up users for DB2 to work with WebSphere Portal.

Before you begin: You should have completed Installing DB2.

- **Prerequisites**
  - Installing DB2

For all databases, use one user with administrative rights on the operating system and the DB2 installation. This user can be the database administrative user that is created automatically by the DB2 installation program. This user is the database configuration user that will be used for configuration tasks: creating database tables and performing database transfer. If you choose to have WebSphere Portal also create the databases, the database user should be given `SYSADM` rights. You only need to manually create an administrator ID when you do not want to use an existing DB2 administrator ID.

A common user name is `db2inst1`, but you can assign any user name as long as it has administrative access and follows the limitations listed here. Do not change the user name after creating it.

The limitations on user names are:

- User names can contain one to eight characters.
- Group and instance names can contain one to eight characters.
- Names cannot be any of the following: `users` `admins` `guests` `public` `local`
- Names cannot begin with: `IBM` `SQL` `SYS`
- Names cannot include accented characters.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Following are the basic steps to create new users and grant privileges. For more information, refer to the DB2 product documentation.

1. From the DB2 Control Center, expand the object tree until you find the DB Users folder.
2. Right-click the DB Users folder and select **Create/Add**. The Create DB User notebook opens.
3. In the User name field, type a user ID.
4. Assign an authority for the user.
5. Click **OK**.

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Installing DB2

**Next topic:** Creating remote databases
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before creating these databases, note the following information:

- Use IBM® DB2 Universal Database™ Enterprise Server Edition JDBC driver, JCC, type 4.

- If the DB2 JDBC type 4 driver is used, only the instructions on the remote server are required. You do not need to install the DB2 client software, and you do not need to complete the steps related to the DB2 client.

- The client software, DB2 Connect, must be correctly configured to connect to the remote DB2 server instance, for example, db2inst1.

- These instructions assume that a remote DB2 server and DB2 Connect are already installed and running. For information on installing DB2 Connect, see the DB2 product documentation.

- **Prerequisites**
  - Installing DB2
  - Create users

To create a database, you must be a DB2 System Administrator with sufficient database privileges (SYSADM or at a minimum SYSCtrl).

1. Log in to the DB2 server system as a user with sufficient database privileges.
2. Initialize a DB2 command environment by opening a command prompt and typing `su - db2inst1`, where `db2inst1` is the database user. The prompt changes to your operating system shell prompt, for example: $.
   In this mode, you must type `db2` at the beginning of each command and use double quotation marks (""") around the entire command. The following example shows how to use the double quotes; it is not an actual command that you run:
   ```
   db2 "CREATE REGULAR TABLESPACE SMS PAGESIZE 4 K MANAGED BY SYSTEM USING ('sms') BUFFERPOOL SMSPOOL"
   ```

   **Note:** If you are using the Command Line Processor (CLP), refer to your DB2 documentation for details. The command prompt is `db2=>`. In this mode, commands can be entered without the `db2` prefix or the double quotation marks.

   However, the following steps assume you are not using the CLP and are entering commands from your operating system shell prompt, for example: $.

3. Run the following commands on the DB2 server system to configure the DB2 database instance:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Description</th>
</tr>
</thead>
</table>
   | **DB2**     | db2set DB2_RA_TO_RS=YES
                | DB2_EVALUNCOMMITTED=YES
                | dbset DB2_INLIST_TO_NLJN=YES
                | db2 "UPDATE DBM CFG USING query_heap_sz 32768"
                | db2 "UPDATE DBM CFG USING maxagents 500"
                | db2 "UPDATE DBM CFG USING sheapthres 0"

4. **(Important)** Failure to complete this step will result in an unsuccessful database transfer. Run the following commands on the DB2 server system to create the necessary databases:

   - Replace `dbname` with the actual name of the database. Run the commands and each time replace `dbname` with the actual values for release, community, customization, Java Content Repository, Feedback, and Likeminds. You will need to run the commands once for each database for a total of six times.

   **Remember:** DB2 database names cannot
exceed eight characters. Therefore, consider using these database names: release, commun, custom, jcrdb, fdbkdb, and lmdb.

```
db2 "CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192"
db2 "UPDATE DB CFG FOR dbname USING applheapsz 4096"
db2 "UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024"
db2 "UPDATE DB CFG FOR dbname USING stmtheap 32768"
db2 "UPDATE DB CFG FOR dbname USING dbheap 2400"
db2 "UPDATE DB CFG FOR dbname USING locklist 1000"
db2 "UPDATE DB CFG FOR dbname USING logfilsiz 4000"
db2 "UPDATE DB CFG FOR dbname USING logprimary 12"
db2 "UPDATE DB CFG FOR dbname USING logsecond 20"
db2 "UPDATE DB CFG FOR dbname USING logbufsz 32"
db2 "UPDATE DB CFG FOR dbname USING avg_appls 5"
db2 "UPDATE DB CFG FOR dbname using AUTO_MAINT off"
```

Complete the following:

5. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (jcrdb).

- `jcrdb` is the name of the database used to store user data and objects
- `jcr` is the jcr user for `jcrdb`. Note: This value can be replaced with any ID that has administrative authority.
- `dbpassword` is the password for the jcr user for the jcrdb

```
db2 "CONNECT TO jcrdb USER jcr USING dbpassword"
db2 "CREATE BUFFERPOOL ICMLSFREQBP4 SIZE 1000 PAGESIZE 4 K"
db2 "CREATE BUFFERPOOL ICMLSVOLATILEBP4 SIZE 16000 PAGESIZE 4 K"
db2 "CREATE BUFFERPOOL ICMLSMAINBP32 SIZE 16000 PAGESIZE 32 K"
db2 "CREATE BUFFERPOOL CMBMAIN4 SIZE 1000 PAGESIZE 4 K"
db2 "CREATE REGULAR TABLESPACE ICMLFQ32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLFQ32') BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMLNF32 PAGESIZE 32 K MANAGED BY SYSTEM USING ('ICMLNF32') BUFFERPOOL ICMLSMAINBP32"
db2 "CREATE REGULAR TABLESPACE ICMVFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMVFQ04') BUFFERPOOL ICMLSVOLATILEBP4"
db2 "CREATE REGULAR TABLESPACE ICMSFQ04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('ICMSFQ04') BUFFERPOOL ICMLSFREQBP4"
db2 "CREATE REGULAR TABLESPACE CMBINV04 PAGESIZE 4 K MANAGED BY SYSTEM USING ('CMBINV04') BUFFERPOOL CMBMAIN4"
```

For JDBC Type 2 connections only: On DB2 Connect, use a text editor to open the `/etc/services` file. If it does not specify the DB2 connection service port, add the following text to specify the port for the remote DB2 instance:
```
db2c_ db2inst1:port1/tcp # DB2 connection service port
```
where `db2inst1` is the name of the DB2 instance ID on the system, and `port1` with the actual port number that is
assigned to the DB2 connection service in your DB2 server installation. The connection service port on the DB2 Client system, WebSphere Portal server, must match the connection service port on the DB2 server. The ports should match by number but not necessarily by name.

C. Set up the correct service name by entering the following command on the DB2 server system:

```
db2 "UPDATE DBM CFG USING svcename svce_name" where svce_name is the connection service port name that is specified above.
```

D. For JDBC Type 2 connections only: On DB2 Connect, set DB2COMM to TCP/IP by using the db2set command

```
db2set DB2COMM=tcpip.
```

E. For JDBC Type 2 connections only: Catalog the TCP/IP node with the IP address of the remote database server on DB2 Connect:

```
db2 "catalog tcpip node remote_db_node_alias remote database_server_node server connection_service_port" where:
- remote_db_node_alias is the alias name of the database server that you are defining for the WebSphere Application Server node name. The alias name can contain one to eight characters.
- database_server_node is the fully qualified host name of your database server system.
- connection_service_port is the name of the DB2 connection service port that is configured in the /etc/services file on the database server system.
```

F. For JDBC Type 2 connections only, catalog the WebSphere Portal databases on DB2 Connect, where:

- remote_db_name_domain, is the cataloged name of the databases on the server system for each domain.
- domain_alias_name, is the database alias names that you are defining.
- remote_db_node_alias is the name that was used previously when you cataloged the TCP/IP node in the previous step.

The alias for each database must be different from the actual database name and can only contain up to eight characters.

```
db2 "catalog db remote_db_name_release as release_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_community as comm_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_customization as cust_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_fdbkdb as fdbkdb_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_lmdb as lmdb_alias_name at node remote_db_node_alias"

db2 "catalog db remote_db_name_jcrdb as jcrdb_alias_name at node remote_db_node_alias"
```

G. For JDBC Type 2 connections only: Log out of DB2 Connect by entering `db2 "terminate"`.

H. For JDBC Type 2 connections only, on DB2 Connect, test your remote connection by issuing the following command in the DB2 command window:

```
db2 "connect to alias_name user username using password", where alias_name is the alias name that you defined above, username is the database user, and password is the password assigned to the database user.
```

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Create users  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `IN` and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`
   
   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.

5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Creating remote databases  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as **release.DbName**, **jcr.DbName**, **feedback.DbName**, and **likeminds.DbName**. For example:

  - `release.DbName` = `release`
  - `jcr.DbName` = `jcrdb`
  - `feedback.DbName` = `fdbkdb`
  - `likeminds.DbName` = `lmdb`
  - `community.DbName` = `commdb`
  - `customization.DbName` = `custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
- dbdomain(DbType
- dbdomain(DbName
- dbdomain(DbUrl
- dbdomain(DbSchema

If you use the same values for all four properties across the release, customization, community, and JCR domains, the
database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not
the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In
other words, this value must be unique for the database domain.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out
the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each
instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your
environment.
   A. For dbdomain(DbType, type db2.
   B. For dbdomain(DbName, type the name of the WebSphere Portal domain database. Notes:
      - This value is also the database element in the dbdomain(DbUrl property.
      - This value is the TCP-IP alias for the database.
   C. For dbdomain(DbSchema, type the schema name of the database domain. Note: Review your target database
      management system documentation to define a valid schema name. Some database management systems have
      schema name restrictions that you need to understand.
   D. For dbdomain.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate
      with its databases. Do not use the following reserved words:
         - releaseDS
         - communityDS
         - customizationDS
         - jcrDS
         - lmdbDS
         - feedback
   E. For dbdomain(DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value
      must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should
      match the value of DbName.
   F. For dbdomain(DbUser, type the user ID for the database administrator.
   G. For dbdomain(DbPassword, type the password for the database administrator.
   H. Optional: For dbdomain(DbRuntimeUser, type the user ID of the database user that should be used by WebSphere
      Portal to connect to the database at runtime.
   I. If dbdomain(DbRuntimeUser is specified, you must set dbdomain(DbRuntimePassword to be the password of the
      runtime database user.
   J. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation
      of the database.
K. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

L. For `dbdomain.XDbName`, type the database loop back alias that needs to be set if you plan to use the `create-database` task. **Note:** Required only for local databases using a JDBC Type 2 driver.

M. For `dbdomain.DbNode`, type the value for the node database. Set this value if you want to call `create-database`. **Note:** Required only for local databases.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domain.DbType`, type of the database you are currently configured to use. The value for `source.domain(DbType)` is Derby by default.

B. For `source.domain.DbName`, type the name of the database domain you are currently using.

C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domain.DbUrl`, type the url currently used to access your database.

F. For `source.domain.DbUser`, type the name of the user accessing this database.

G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplcDbType.properties`.

   A. For `db2.DbDriver`, type the name of the JDBC driver class.

   B. For `db2.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `db2.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.
Configuring JCR collation support

View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

1. Stop the WebSphere Portal server:
   ```
   ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```

2. If using a remote DB2 server, copy the following files from the WebSphere Portal server to a temporary directory on the remote DB2 server:
   ```
   PortalServer_root/jcr/prereq.jcr/config/collation.jar
   PortalServer_root/jcr/prereq.jcr/config/registerCollationUDFTemplate.sql
   ```

3. Set up collation on the database where the JCR domain is located.
   A. Change to the directory `db2_instance_owner_home/sqlib/function`.
   B. Execute the command: **Remote DB2**:
      ```
      db2_instance_owner_home/sqlib/java/jdk/bin/jar -xvf temporary location/collation.jar icm/CollationUDF.class
      ```
      **Local DB2**:
      ```
      db2_instance_owner_home/sqlib/java/jdk/bin/jar -xvf PortalServer_root/jcr/prereq.jcr/config/collation.jar icm/CollationUDF.class
      ```
   C. If using a local DB2, change to the directory `wp_profile_root/PortalServer/jcr/config`. If using a remote DB2, change to the temporary directory where you copied the files in a previous step.
   D. Open the file `registerCollationUDFTemplate.sql` and change all `SCHEMA` references to the JCR schema; for example, `JCR`. The value set for `SCHEMA` should match the value set for the `jcr.DbSchema` property. You specify `jcr.DbSchema` in the configuration file `wkplc_comp.properties` when you modify database properties.

4. Connect to the JCR database by running `db2` connect to `<jcrdb>` user `<userid>` using `<password>`. Execute the following command. **Remote DB2**:
   ```
   db2 -tvf temporary location/registerCollationUDFTemplate.sql
   ```
   **Local DB2**:
   ```
   db2 -tvf wp_profile_root/PortalServer/jcr/config/registerCollationUDFTemplate.sql
   ```

5. Edit the `icm.properties` file, located in `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` directory. Add the following section to the end of the file:
   ```
   # Enable/Disable collation support for all DB2 platforms
   ```
# Disabled by default
jcr.query.collation.db2.enabled = true

# Database specific collation mappings
# These mappings apply map a Java locale name into a collation name
# supported by the underlying database.
# Example mappings for DB2 platform

# English
jcr.query.collation.en = en

# Swedish
jcr.query.collation.sv = sv

jcr.query.collation.zh = zh
jcr.query.collation.de = de
jcr.query.collation.da = da
jcr.query.collation.hu = hu
jcr.query.collation.jp = jp

6. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```
Configure WebSphere Portal to use DB2

View the steps to manually transfer data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
- Ensure that the following prerequisites are met:
  - Supported database software is installed.
  - Databases and users are set up.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties

**Tips:**
- To run these tasks as a non-root user, you must first run the task chown -R non-root_userWebSphereDir.
- If you are transferring from Oracle, the **open_cursors** setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

**Steps for transferring data to another supported database**

1. **Steps for transferring data to another supported database**
   - If you are running a type 2 connection, before transferring data edit the **db2cli.ini** file. Failure to follow these steps will cause the database transfer to hang at the task **action-process-constraints**.
     - **A.** Locate the file `/home/db2inst1/sqlib/cfg/db2cli.ini`.
     - **B.** Add the following to the end of the file. Leave an empty line after **ReturnAliases=0.[COMMON]**
       ```
       [COMMON]
       DYNAMIC=1
       ReturnAliases=0
       ```

2. **Steps for transferring data to another supported database**
   - Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.

3. **Steps for transferring data to another supported database**
   - Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2.
     ```
     /home/db2inst1/sqlib/db2profile
     where db2inst1 represents your database instance**Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.
     ```

4. **Steps for transferring data to another supported database**
   - Enter the following commands to validate configuration properties...
     ```
     ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
     ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
     ```

5. **Steps for transferring data to another supported database**
   - From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

---

**Operating systems:** AIX, HP-UX, i5/OS, Linux, Solaris, Windows
6. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

7. Transfer the database:
   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   
   A. Change to the directory `wp_profile_root/ConfigEngine`.
   
   B. Enter the following command: 
   ```
   ./ConfigEngine.sh database-transfer -DWasPassword=password
   ```
   **Note:**
   - To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   ```
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```
   - If you have been storing data in IBM® Derby for a long time, database transfer could fail with OutOfMemory exceptions. If database transfer fails, add the following property to the command in this step: 
   ```
   ./ConfigEngine.sh database-transfer -DDbtJavaMaxMemory=1536M -DWasPassword=password
   ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

8. After transferring the database tables, perform a `reorg` check to improve performance. Perform this step for each database alias in the property file.

   A. Connect to a database with the following command:
   ```
   db2 connect to database_alias user db2admin_userid using password
   ```
   **Note:** Additional options might be required if additional security has been installed. Refer to DB2 Universal Database commands by example for links to the command reference.

   B. After it is connected, run the following commands from the DB2 prompt:
   ```
   db2 reorgchk update statistics on table all > xyz.out
   ```
   Look in the reorg column for entries marked with a * (star or asterisk) in the file `xyz.out`. For each line with a *, note the `tablename` and run the following command for each `tablename`:
   ```
   db2 reorg table tablename db2 terminate db2rbind database_name -l db2rbind.out -u db2_admin -p password
   ```
   D. The output file `db2rbind.out` is only created when there is an error for the `db2rbind` command.

9. Change to the directory `wp_profile_root/bin`.

10. Enter the following command to start the WebSphere Portal server:
    ```
    ./startServer.sh WebSphere_Portal
    ```

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Configuring JCR collation support

**Next topic:** Configuring DB2 for large file handling in Web Content Management
Configuring DB2 for large file handling in Web Content Management

If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configure WebSphere Portal to use DB2

**Note:** You only need to perform these steps if you are using Web Content Management.

1. Log into the WebSphere Application Server administrative console.
2. Click **Resources > JDBC > Data sources**.
3. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
4. Select the name of the data source that is defined in `wkplc_comp.properties` for the JCR database domain. The default data source is `wpdbDS`.
5. Click **Custom properties**.
6. Ensure that the `fullyMaterializeLobData` property is set to `false`.

---

**Parent topic:** Configuring WebSphere Portal to use DB2

**Previous topic:** Configure WebSphere Portal to use DB2

**Next topic:** Changing driver types
Changing driver types

WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Before you begin, ensure that the following conditions are met:

- The WebSphere Portal database has been successfully transferred to DB2 using the database-transfer configuration task.
- The files wkplc_comp.properties and wkplc_dbtype.properties have been modified to set the correct values for the DB2 drivers that you are switching to:

  In the file wkplc_comp.properties set each `<Domain>.DbUrl` property using the following formats:
  # db2 (type 2):        { jdbc:db2:wpsdb }
  # db2 (type 4):        { jdbc:db2://<YourDatabaseServer>:50000/wpsdb:returnAlias=0; }

  In the file wkplc_dbtype.properties set the `db2.DbLibrary` property using the following format:
  # For DB2 Type 2 driver use `<SQLLIB>/java/db2java.zip`
  # For DB2 Type 4 driver use `<SQLLIB>/java/db2jcc.jar:<SQLLIB>/java/db2jcc_license_cu.jar`

  In the file wkplc_dbtype.properties set the `db2.DbDriver` property using the following format:
  # For DB2 Type 2 driver use COM.ibm.db2.jdbc.app.DB2Driver
  # For DB2 Type 4 driver use com.ibm.db2.jcc.DB2Driver

  **Note:** If WebSphere Portal is installed on the same machine as the DB2 server and you switch from a JDBC Type 4 connection to a JDBC Type 2 connection, verify that you have created the alias names for the DB2 databases as described in Creating remote databases and that the alias names are specified for the databases in the file wkplc_comp.properties.

  When switching from a JDBC Type 2 connection to a JDBC Type 4 connection, remove the database alias names and refer to the databases directly. This is required because of a limitation in the DB2 Universal JDBC driver.

- **Prerequisites**

  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configure WebSphere Portal to use DB2
  - Configuring DB2 for large file handling in Web Content Management

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Using a JDBC Type 2 driver only, export the DB2 user profile that you created when installing DB2 onto the administrative user using the following command. This command gives that administrative user rights over DB2. 

   ```
   /home/db2inst1/sqlib/db2profile
   ```

   where `db2inst1` represents your database instance

   **Note:** You must complete this step before running database tasks and before enabling security to create a suitable JDBC driver.

3. Enter the following commands to validate configuration properties:

   ```
   /ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```
4. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>./stopServer.sh server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

6. Change to the directory `wp_profile_root/ConfigEngine`.

7. To change from one supported driver to the other, run the following task to connect the database, including only the domains that require the switch:

   ```bash
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
  
   ```

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server:

   ```bash
   ./startServer.sh WebSphere_Portal
   ```

Parent topic: Configuring WebSphere Portal to use DB2

Previous topic: Configuring DB2 for large file handling in Web Content Management
Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

1. **Installing DB2 for z/OS**
   - View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

2. **Creating users**
   - Complete this procedure to set up users for IBM DB2 Universal Database™ for z/OS® to work with IBM WebSphere Portal.

3. **Creating remote databases**
   - A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

4. Optional: **Creating the Java Content Repository database**
   - View information on setting up your Java Content Repository database to work with WebSphere Portal.

5. Optional: **Assigning custom table spaces**
   - The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

6. **Modifying database properties**
   - This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

7. **Configuring WebSphere Portal to use DB2 for z/OS**
   - View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing DB2 for z/OS

View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

The following prerequisites must exist separately from the WebSphere Portal installation:

- If you are using the DB2 Legacy Type 2 JDBC driver, configure your DB2 Connect client with the following commands:
  - `db2 update dbm cfg using tp_mon_name WAS`
  - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name for the machine where the DB2 Connect client is installed (same as portal machine).

- If you are using the DB2 Legacy Type 2 JDBC driver, enable extended shared memory usage with the following commands:
  - `export EXTSHM=ON`
  - `db2set DB2ENVLIST=EXTSHM`
  - `db2start`
  - To make the change permanent, you must add the environment variable by adding the following to the `profile.env` file:
    ```
    DB2ENVLIST='EXTSHM'
    ```
  - in `/home/db2inst/sqllib/userprofile add: export EXTSHM=ON`

  **Note:** The shell must be reopened before restarting DB2 for z/OS.

- Both type 2 and type 4 drivers are supported. If you are using the DB2 Legacy Type 2 JDBC driver, the DB2 Connect client must be installed on the same machine as WebSphere Portal to connect to the remote database.

- The DB2 subsystem must be on a supported z/OS platform.

- Update the BP8K0 catalog bufferpool to 35,000 buffers before performing database transfer. You should change this value based on your environment. The SYSIBM.SYSDATABASE table resides in this bufferpool and is used extensively by DB2 for z/OS during database transfer.

To use DB2 for z/OS as the database software for WebSphere Portal, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions. Refer to the Planning for DB2 for z/OS topic for additional considerations for configuring DB2 for z/OS as the WebSphere Portal database.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Next topic:** Creating users
Creating users

Complete this procedure to set up users for IBM® DB2 Universal Database™ for z/OS® to work with IBM WebSphere® Portal.

Before you begin: You should have completed Installing DB2 for z/OS.

- **Prerequisites**
  - Installing DB2 for z/OS

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

- If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, you must create a unique database user for each WebSphere Portal instance. By default all database table names include the name of the database user used to access the data. Therefore, to prevent table name conflicts, you must create a unique database user for each WebSphere Portal instance on the shared DB2 for z/OS subsystem.

- Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Use the following steps to grant access permissions to the database users. Repeat these steps for each WebSphere Portal instance you are setting up.

1. Create all database user IDs in the security product you are using on z/OS. For `jcrschema`, the database schema name for IBM Java Content Repository data, create a group and connect it to the database user ID for Java Content Repository data, `jcr`. The following sample shows the RACF definition of such a user ID and group, where `jcr` is the database user ID for Java Content Repository data, `yourDefaultUserGroup` is your default RACF group for database user IDs, `jcrschema` is the database schema name for Java Content Repository data, and `yourDefaultGroup` is your default RACF group for groups. If you have some other security product such as Top Secret or ACF2 instead of RACF, translate the sample RACF definition into the appropriate syntax before running the job.

   ```racf
   ADDUSER jcr DFLTGRP(yourDefaultUserGroup) NAME('WAS DB2 ACCESS USER')
   PW USER(jcr) NOINTERVAL
   ALU jcr PASSWORD(********) NOEXPIRED
   ADDGROUP jcrschema SUPGROUP(yourDefaultGroup)
   CONNECT jcr GROUP(jcrschema)
   ```

2. Run the following SQL statements using a tool like SPUFI while logged on to the DB2 subsystem to grant appropriate rights on the newly created databases. If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, be sure to use the database user associated with the database user ID you created for each WebSphere Portal instance you are setting up. (C) create/alter tablespaces
   (C) create/alter tables
   (C) create/alter indice;
   (C+R) read/write data
   (C) - at configuration time
   (R) - at runtime

Note: Make sure your vmmdb user follows these same standards.

WebSphere Portal instance you are setting up.

where:
- releasenameonzos, communitynameonzos, customizationnameonzos, and releaseusr, communityusr, customizationusr represent the databases and database users, respectively, of the WebSphere Portal instance you are setting up. (These users must be created on the host system.)

- jcrdbnameonzos and jcr are the database and database user, respectively, for Content Repository data.
- feedbackdbnameonzos and feedback are the database and database user, respectively, for Feedback data.
- lmdbnameonzos and lmdbusr are the database and database user, respectively, for Likeminds data.
- jcrschema is the database schema name for Content Repository data.

3. Grant the necessary access rights to all users who might require them. Depending on the architecture that you choose, these users might include Java Content Repository and Feedback users.

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Installing DB2 for z/OS
Next topic: Creating remote databases
Creating remote databases

A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

Before you begin, complete the following prerequisites:

- These instructions assume that you will use a local IBM® DB2 Universal Database™ Enterprise Server Edition Connect to connect to a remote IBM DB2 Universal Database for z/OS® server, and that IBM WebSphere® Application Server, WebSphere Portal, and DB2 Connect will be installed on the same machine.

- To run SQL statements, you can use a tool like SPUFI. The specified statements include CREATE STOGROUP, CREATE DATABASE and CREATE TABLESPACE. For CREATE STOGROUP you have to replace the icmvolumes and icmvcat variables with volume serial numbers and a catalog name for your environment. For CREATE TABLESPACE you can specify a specific BUFFERPOOL. Refer to the DB2 for z/OS SQL Reference for a description of these options.

- Ensure that a TEMP database is created for your subsystem. You can use the following statements to create a TEMP database:
  
  ```sql
  CREATE DATABASE db_name AS TEMP;
  CREATE TABLESPACE ts_name IN db_name;
  ```

- Log on to the DB2 subsystem on the host server. DB2 system administrator rights are needed to create the databases.

- Replace variables as follows:

  - releasenameonzos, communitynameonzos, and customizationnameonzos are the WebSphere Portal databases for WebSphere Portal and Member Manager data.
  - fdbkdbnameonzos and fdbkdbts are the database and table space, respectively, for Feedback data.
  - lmdbnameonzos and lmdbs are the database and table space, respectively, for LikeMinds data.

- Because large objects are stored in columns that can become very large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for tablespaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see Technote 1306637, Managing LOB logging in DB2 for z/OS.

- **Prerequisites**
  - Installing DB2 for z/OS
  - Creating users

Use the following steps to set up WebSphere Portal with a remote instance of DB2 for z/OS. Refer to Planning for DB2 for z/OS for a list of databases and table space names. If you are configuring multiple WebSphere Portal instances to use a single DB2 subsystem, be sure to use the database and table space names associated with the WebSphere Portal instance you are setting up.

1. ```sql
   CREATE DATABASE releasenameonzos CCSID UNICODE;
   ```

2. ```sql
   CREATE DATABASE communitynameonzos CCSID UNICODE;
   ```

3. ```sql
   CREATE DATABASE customizationnameonzos CCSID UNICODE;
   ```

4. Execute the steps in the topic Creating the Java Content Repository database.

5. ```sql
   CREATE DATABASE fdbkdbnameonzos CCSID UNICODE;
   CREATE TABLESPACE fdbkdbts IN fdbkdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500 LOCKSIZE ROW;
   ```

6. ```sql
   CREATE DATABASE lmdbnameonzos CCSID UNICODE;
   ```
8. CREATE TABLESPACE lmdbts IN lmdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500;
Creating the Java Content Repository database

View information on setting up your Java Content Repository database to work with WebSphere Portal.

First, you need to create multiple databases for scalability.

The IBM Java Content Repository database grows in size as the IBM® WebSphere® Portal server is used. To support this growth, which includes the dynamic creation of many new tables within the database, the WebSphere Portal server allows you to create multiple databases within a single IBM DB2 Universal Database™ for z/OS® subsystem. A minimum of two databases is recommended, but more can be created if necessary. A single database setup is not recommended; it will quickly become constrained. See the Performance guides on the product documentation Web site for more information.

Each database that is created must begin with a common prefix; there is no convention required for the remainder of the name. For example, to create \( xx \) number of databases, you may choose to use the following commands:

\[
\text{CREATE DATABASE JCRDB01}
\]

\[
\text{CREATE DATABASE JCRDB02}
\]

\[
\ldots
\]

\[
\text{CREATE DATABASE JCRDBxx}
\]

In this case, \( JCR \) is the common prefix. You also have to select a maximum number of user-defined tables (UDT) that each database will be allowed to hold; the recommended value is 400.

- **Prerequisites**
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

A sample script of the commands that you can use to create the Java Content Repository database in your DB2 for z/OS installation is shown below. The sample demonstrates the creation of a single database. To follow the recommendation of creating at least two databases, duplicate the commands for each additional database as indicated below. Find a template of these commands in the file `PortalServer_root installer/wp.config/config/templates/db/db2_zos/jcr_sample.sql`.

**Notes:**
- It is not necessary to duplicate every tablespace definition in every database.
- In order to run the commands shown in the sample, you must know the database name and the IDs of the MVS volumes where the Java Content Repository database tables will be stored.
- Edit the template file for your installation environment before running the commands shown in the sample:
  - Replace `jcrdbnameX` with the name of the database. Remember that each database name must begin with a common prefix.
  - Replace `stogroup` with the name of your storage group.
  - Replace `icmvolumes` with the IDs of the MVS volumes where the Java Content Repository database tables will be stored. These values are assigned by the database administrator.
  - Replace `icmvcat` with the name of the virtual catalog.
  - Replace `jcr` with the name of database user ID.
  - Replace `4kbp` with the name of your 4K bufferpool.
  - Replace `32kbp` with the name of your 32K bufferpool.
  - Replace `jcrschema` with the schema name of your Java Content Repository domain.
--DROP DATABASE jcdbNameX
--DROP STOGROUP stogroup
--DROP ALIAS jcrschema.ICMFICTITIOUS

CREATE STOGROUP stogroup VOLUMES (icmvolumes) VCAT icmvcat
GRANT USE OF STOGROUP stogroup to jcr

CREATE DATABASE jcdbNameX STOGROUP stogroup BUFFERPOOL 4kbp INDEXBP 4kbp CCSID UNICODE

**Note:** The following two tablespace commands must be created in every database:

CREATE TABLESPACE ICMLFQ32 IN jcdbNameX USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 32kbp CCSID UNICODE
CREATE TABLESPACE ICMTSQ04 IN jcdbNameX USING STOGROUP stogroup PRIQTY 500 SECQTY 200 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 4kbp CCSID UNICODE

**Note:** The following tablespaces are required in the first database only:

CREATE TABLESPACE ICMLFQ04 IN jcdbNameX USING STOGROUP stogroup PRIQTY 500 SECQTY 200 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 4kbp CCSID UNICODE

Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.
- When using IBM® DB2 Universal Database™ for z/OS® as a data store, WebSphere Portal requires that its indexes are not padded. Therefore, you must set the DSNZPARM parameters to `RETVLCFK=NO` or `PADIX=NO`, or both.

**Prerequisites**
- Installing DB2 for z/OS
- Creating users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a table space to each `.tablespace` entry in the mapping file. Assignments to `.indexspace` entries are ignored. The table space name must be qualified by the database name and prepended by the keyword `IN` and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Previous topic:** Creating the Java Content Repository database

**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custdb
- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

**Note:** To successfully transfer data from the JCR domain, you must use the DDF location value for the value of `jcr.DbName` field when setting up IBM DB2 Universal Database™ for z/OS®. You can locate the name of the DDF location value in the IBM DB2 Universal Database for z/OS sdsnsamp dataset, member DSNTIJUZ, or by running the following DB2 command:
```
db2 subsystem prefix display ddf
```

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   
   A. For `dbdomainDbType`, type `db2_zos`.
   
   B. For `dbdomainDbName`, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the `dbdomainDbUrl` property.
   
   C. For `dbdomainDbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   
   D. For `dbdomainDbNameOnZos`, type the name of the WebSphere Portal database on DB2 for z/OS. **Note:**
      - If running DB2 for z/OS as a remote database, set the value to the name of the remote database for the domain.
      - If WebSphere Portal is running on z/OS with DB2 for z/OS, set the value equal to the value of `DbName`.
   
   E. For `dbdomainDataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - `releaseDS`
      - `communityDS`
      - `customizationDS`
      - `jcrDS`
      - `lmdbDS`
      - `feedback`
   
   F. For `dbdomainDbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of `DbName`.
   
   G. For `dbdomainDbUser`, type the user ID for the database administrator.
   
   H. For `dbdomainDbPassword`, type the password for the database administrator.
I. For `dbdomain(DbTablespace`, type the name of the DB2 for z/OS tablespace.
J. For `dbdomain(DbStorageGroup`, type the name of the storage group for the database.
K. For `dbdomain(DbVolumes`, type the volumes for the database.
L. For `dbdomain(DbVcat`, type the VCAT for the database.
M. For `dbdomain(Db4KBufferPoolName`, type the 4K bufferpool name for the database.
N. For `dbdomain(Db32KBufferPoolName`, type the 32K bufferpool name for the database.
O. For `dbdomain(DbIndex4KBufferPoolName`, type the 4K bufferpool name for the database. If you choose to use the default bufferpool value BP3, verify that this bufferpool is active.
P. For `dbdomain(TablespaceTrackMod`, set the value to determine TRACKMOD attribute of all tablespaces to use the specified value. Refer to the DB2 for z/OS documentation before changing this value.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.
A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.
B. For `source.domainDbName`, type the name of the database domain you are currently using.
C. For `source.domainDbSchema`, type current schema identifier for objects within the database for this domain.
D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For `source.domainDbUrl`, type the url currently used to access your database.
F. For `source.domainDbUser`, type the name of the user accessing this database.
G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkpic_dbtype.properties`.
A. For `db2_zos.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.
B. For `db2_zos.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
C. For `db2_zos.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.
D. For `db2_zos.DbDriverType`, type the number of the driver type for the database.
E. For `db2_zos.DbLocationName`, type the DB2 location name. This value is set in the installation job DSNTIJUZ.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.
A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Previous topic:** Assigning custom table spaces

**Next topic:** Configuring WebSphere Portal to use DB2 for z/OS
Configuring WebSphere Portal to use DB2 for z/OS

View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases
  - Modifying database properties

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.
   
   A. Locate the file /home/db2inst1/sqllib/cfg/db2cli.ini.
   
   B. Add the following to the end of the file. Leave an empty line after ReturnAliases=0.[COMMON]
      
      DYNAMIC=1
      ReturnAliases=0

2. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.

3. Enter the following commands to validate configuration properties.
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password

4. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td>./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

6. Transfer the database:
   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   
   A. Change to the directory wp_profile_root/ConfigEngine.
   
   B. Enter the following command:
      ./ConfigEngine.sh database-transfer -DWasPassword=password

      **Note:** To select specific database domains to transfer, modify the -DTransferDomainList specified in the command
to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter
the following command: 

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and
`wkplc_dbtype.properties` files and then repeat this step.

7. From the command line processor, reset the check pending status on the WebSphere Portal table spaces listed here.

CHECK DATA is a DB2 batch utility that is invoked through JCL or through the DB2 utility panels. Type the following
utility commands to check pending status:

```
check data tablespace releasenameonzos.TS280A
check data tablespace releasenameonzos.TS300A
check data tablespace releasenameonzos.TS2110A
check data tablespace releasenameonzos.TS830A
check data tablespace communitynameonzos.TS8000B
check data tablespace communitynameonzos.TS8011B
check data tablespace communitynameonzos.TS280B
check data tablespace customizationnameonzos.TS2110C
check data tablespace jcrdbnameonzos.ICMSFQ04
check data tablespace jcrdbnameonzos.TS2110D
```

where `releasenameonzos`, `communitynameonzos`, and `customizationnameonzos` are the names of your WebSphere
Portal databases, and `jcrdbnameonzos` is the name of your JCR database. Refer to the *Utility Guide and Reference for
DB2 for z/OS* for additional details.

8. Run the `RUNSTATS` utility as shown in the following example:

```
LISTDEF JCRDB2OS INCLUDE TABLESPACE JCRDB2OS.* BASE
RUNSTATS TABLESPACE LIST JCRDB2OS INDEX(ALL) KEYCARD TABLE(ALL)
LISTDEF JCRDB01 INCLUDE TABLESPACE JCRDB01.* BASE
RUNSTATS TABLESPACE LIST JCRDB01 INDEX(ALL) KEYCARD TABLE(ALL)
...```

9. Start the WebSphere Application Server.

10. Verify that the WebSphere Portal application server is running by opening the following URL in a browser:

```
http://hostname.companyname.com:port_number/wps/portal
```

where `hostname.companyname.com` is the fully qualified host name of the machine where WebSphere Portal is running and `port_number` is the transport port that is created by
WebSphere Application Server.

If you have performed database transfer in a clustered environment, you must explicitly copy the `wp_profile_root
/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node on which the `database-transfer` task
was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values
specified in the `icm.properties` file.

1. Stop the portal server on the secondary node.
2. Copy the `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm/icm.properties` file from the primary node and
   replace the `icm.properties` file on the secondary node with the new file from the primary node.
3. Start the portal server on the secondary node.

Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

1. Installing Oracle
   View information on how to install Oracle for use with WebSphere Portal.

2. Creating users
   View the steps to set up users for Oracle to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle databases to work with WebSphere Portal.

4. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and
   wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create
   databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an
   alternative to automatically setting up the database, you can manually create users and grant privileges.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When
   using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer
   to the target database system.

8. Configure WebSphere Portal to use Oracle
   This section provides information on how to manually transfer data to the Oracle database you have installed and set
   up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an
   alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete
   the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle

View information on how to install Oracle for use with WebSphere Portal.

You can use Oracle as the database software. You must install Oracle separately and before performing a database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle
Next topic: Creating users
Creating users

View the steps to set up users for Oracle to work with WebSphere Portal.

Before you begin:

- You should have installed Oracle.

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**

- Installing Oracle

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Start the Oracle SQL command line processor 'SQL*Plus' by entering `sqlplus /nolog` on the operating system command prompt

2. Log in to the Oracle database by executing command `connect user/password@database name`. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.

3. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, or customization.

   A. Log in to the database in which you want to create the new users.

   B. Create the users that you need in the appropriate databases by entering the following commands in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects. All names must be in lower case.

   ```sql
   SQL> create user releaseusr identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO releaseusr;
   SQL> create user communityusr identified by password
   default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO communityusr;
   SQL> create user customizationusr identified by password
   default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO customizationusr;
   SQL> create user jcr identified by password
   default tablespace user_tablespace temporary tablespace temp_tablespace;
   GRANT UNLIMITED TABLESPACE TO jcr
   ```

4. Connect to the Feedback database:

   A. Enter the following command: `SQL> connect`
B. Enter user-name: username/password@dbname where username is an existing administrative user in the database. For example, system/manager@fdbkdb will log the administrative user system with a password of manager into the fdbkdb database.

C. Create the Feedback user:

```
SQL> create user feedback identified by password
    
default tablespace user_tablespace
    
temporary tablespace temp_tablespace;
    
GRANT UNLIMITED TABLESPACE TO feedback
```

D. Log out of the command line tool using the command SQL> exit.

5. Connect to the LikeMinds database:

A. Enter the following command:

```
SQL> connect
```

B. Enter user-name: username/password@dbname, where username is an existing administrative user in the database.

For example, system/manager@lmdb will log the administrative user system with a password of manager into the lmdb database.

C. Create the LikeMinds user:

```
SQL> create user lmdbusr identified by password
    
default tablespace user_tablespace
    
temporary tablespace temp_tablespace;
    
GRANT UNLIMITED TABLESPACE TO lmdbusr
```

D. Log out of the command line tool using the command SQL> exit.

6. Perform the following steps to verify that you can connect to the database with the user ID and password that you just created:

A. Enter the SQL> connect command to connect to the content database.

B. Enter user-name: username/password@dbname, where username is an existing administrative user in the database. For example, system/manager@jcrdb will log the administrative user system with a password of manager into the Oracle database.

Parent topic: Configuring WebSphere Portal to use Oracle

Previous topic: Installing Oracle

Next topic: Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal. For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNİCODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:
- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNİCODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:

  - db_block_size = 8192 bytes
  - db_cache_size = 307,200 bytes
  - db_files = 1024 files
  - log_buffer = 65536 bytes
  - open_cursors = 1500 cursors
  - pga_aggregate_target = 204,800 bytes
  - pre_page_sga = true
  - processes = 300 processes
  - shared_pool_size = 204,800 bytes

**Note:** If you are using IBM Java Content Repository, the open_cursors value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the parallel_max_servers to 1200.
- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:

  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.

  - **EXACT**
When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

- **Prerequisites**
  - Installing Oracle
  - Creating users

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating users  
**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:

  - `release.DbName` = `release`
  - `jcr.DbName` = `jcrdb`
  - `feedback.DbName` = `fdbkdb`
  - `likeminds.DbName` = `lmdb`
  - `community.DbName` = `commdb`
  - `customization.DbName` = `custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.

   A. For dbdomain.DbType, type oracle.
   B. For dbdomain.DbName, type the name of the WebSphere Portal domain database. \textbf{Note:} This value is also the database element in the dbdomain.DbUrl property.
   C. For dbdomain.DbSchema, type the schema name of the database domain. \textbf{Note:} Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomain.DbName should be the same value used for the dbdomain.DbSchema
      \hspace{1cm} \textbf{Restriction:} The value for dbdomain.DbSchema must equal the value for dbdomain.DbUser.
   D. For dbdomain.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomain.DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. \textbf{Note:}
      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. \textbf{When database transfer is completed,} the WebSphere Portal server will be configured to use this single database server.
F. For `dbdomain.DbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomain.DbUser` must equal the value for `dbdomain.DbSchema`.

G. For `dbdomain.DbPassword`, type the password for the database administrator.

H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.

I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For `source.domain.DbType`, type of the database you are currently configured to use. The value for `source.domain.DbType` is Derby by default.

B. For `source.domain.DbName`, type the name of the database domain you are currently using.

C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.

D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For `source.domain.DbUrl`, type the url currently used to access your database.

F. For `source.domain.DbUser`, type the name of the user accessing this database.

G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

A. For `oracle.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.

B. For `oracle.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For `oracle.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating databases  
**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

**Prerequisites**
- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the setup-database task. The setup-database task requires these folders to create database users. If these folders do not exist, the setup-database task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`.

3. To create the database users, type the following command:

   ```bash
   ./ConfigEngine.sh setup-database -DWasPassword=password
   
   Note: This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:
   
   `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.
   ```

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**
Manually creating users and granting privileges for Oracle
Creating JCR table spaces
This topic provides manual instructions for creating JCR table spaces for Oracle.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.
   
   Ensure that the ' ' is included in the variables when you substitute the values of your environment with these variables.
   
   Important: You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb./data/'&jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '&dbpath./&jcrdb./data/'&jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb./data/'&jcrdb._ICMVFPQ04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb./data/'&jcrdb._ICMSFPQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '&dbpath./&jcrdb./index/'&jcrdb._ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   ```

   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

Parent topic: Configuring WebSphere Portal to use Oracle
Previous topic: Setting up databases
Next topic: Assigning custom table spaces
Assigning custom table spaces
The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespsaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**- Prerequisites**
- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespsaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configure WebSphere Portal to use Oracle
Configure WebSphere Portal to use Oracle

This section provides information on how to manually transfer data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

Tips:

- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory wp_profile_root/ConfigEngine.
2. Enter the following commands to validate configuration properties:
   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```
3. From the same command prompt as the previous steps, change to the directory wp_profile_root/bin.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>./stopServer.sh server1 -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>
5. Transfer the database. **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.

   B. Enter the following command: `./ConfigEngine.sh database-transfer -DWasPassword=password`

   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command: `./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password`

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files. If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example: `SQL> execute dbms_stats.gather_schema_stats(ownname=>'jcr', cascade=> TRUE);`

7. Change to the directory `wp_profile_root/bin`.

8. Enter the following command to start the WebSphere Portal server: `./startServer.sh WebSphere_Portal`
Configuring WebSphere Portal to use Oracle RAC

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:
- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon_(GSD), oracle listeners, and agents.
  - $ gsdctl start
  - $ lsnrctl start
  - $ agentctl start

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle RAC

Next topic: Create users
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:
- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**
- Installing Oracle RAC

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects:

   ```sql
   SQL> create user username identified by password
   default tablespace user_tablespace
   temporary tablespace temp_tablespace;
   ```

   **Tip:** Balance the storage of user objects among tablespaces to prevent running out of space with overuse of `user_tablespace`. Also consider increasing the size of `user_tablespace` when handling a high volume of users.

2. Log in by entering the command `$ sqlplus` in SQL*Plus:

3. Enter the command `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example: `system/manager@wpsdb` will log the administrative user `system` with a password of `manager` into the wpsdb database.

4. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults.

   ```sql
   SQL> create user releaseusr identified by password;
   SQL> create user communityusr identified by password;
   SQL> create user customizationusr identified by password;
   SQL> create user jcr identified by password;
   ```

5. Connect to the content database by entering the command `SQL> connect`.

6. Enter the following, where `username` is an existing administrative user in the database. `user-name: username/password@dbname`. For example, `system/manager@jcrdb` will log the administrative user `system` with a password of `manager` into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the `jcr` user, grant all necessary privileges. If you do not grant privileges, you will receive the error `ICMADMIN lacks CREATE SESSION Privilege logon denied`
when you try to connect with the `jcruser`:

```
SQL> create user jcr identified by password default tablespace users temporary tablespace temp;
```

8. Connect to the Feedback database:

   A. Enter the following command: `SQL> connect`

   B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database.

      For example, `system/manager@fdbkdb` will log the administrative user system with a password of manager into the fdbkdb database.

9. Create the Feedback user:

    `SQL> create user feedback identified by password default tablespace users temporary tablespace temp;`

10. Connect to the LikeMinds database:

    `SQL> connect`

11. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@lmdb` will log the administrative user system with a password of manager into the lmdb database.

12. Create the LikeMinds user:

    `SQL> create user lmdbusr identified by password default tablespace users temporary tablespace temp;`

13. Log out of the command line tool using the command `SQL> exit`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Installing Oracle RAC

**Next topic:** Creating databases
Creating databases

View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal. When creating Oracle RAC databases for use with WebSphere Portal, you should consider the following information:

- The Oracle RAC databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle RAC server will be remote or local to the WebSphere Portal installation.
- If using an earlier version of Oracle RAC (9i or earlier), ensure that Oracle RAC JVM is also installed.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle RAC database in order for WebSphere Portal to communicate with the IBM Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes are:
  
  - `db_block_size` = 8192 bytes
  - `db_cache_size` = 314,572,800 bytes
  - `db_files` = 1024 files
  - `log_buffer` = 65536 bytes
  - `open_cursors` = 1500 cursors
  - `pga_aggregate_target` = 209,715,200 bytes
  - `pre_page_sga` = true
  - `processes` = 300 processes
  - `shared_pool_size` = 209,715,200 bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the IBM Java Content Repository schema.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users

Refer to the following instructions to create tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.

2. Create the tablespaces. **Important:** You must use the same tablespace names listed in the commands. The tablespace names cannot be customized or modified.

   A. Find and edit the SQL script `jcr_ora_tablespaces.sql` in the directory `wp_profile_root/ConfigEngine/work/db/oracle`.

   B. In the define section, replace the following variables with the values from your environment:
      - `jcrdb`
        - Name of the database you created to store user data.
      - `logfile`
        - Location to store the log file.
      - `dbpath`
        - Directory where you created the database.

   C. Set the size, autoextend, and maxsize values according to your environment. For example, you may want to change the maxsize to a set value rather than UNLIMITED. Consult your Database Administrator for more info.
D. Execute the following SQL script:

**Notes:**
- The DBA or a user with sufficient credentials (CREATE tablespace) must execute the script.
- The script will prompt for the database username and password.

```
# sqlplus
SQL> @jcr_ora_tablespaces.sql
```

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Create users
Next topic: Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:

- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:

  - `release.DbName` = release
  - `jcr.DbName` = jcrdb
  - `feedback.DbName` = fdbkdb
  - `likeminds.DbName` = lmdb
  - `community.DbName` = commdb
  - `customization.DbName` = custdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If DbUser, DbUrl, and DbPassword are not the same across domains, the value for DataSourceName must differ from the DataSourceName of the other domains. In other words, this value must be unique for the database domain.

If you are using a single-database, single-user, and multi-schema database transfer, the user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.
   A. For dbdomainDbType, type oracle.
   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomainDbUrl property.
   C. For dbdomainDbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomainDbName should be the same value used for the dbdomainDbSchema
      Restriction: The value for dbdomainDbSchema must equal the value for dbdomainDbUser.
   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
F. For `dbdomain.DbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomain.DbUser` must equal the value for `dbdomain.DbSchema`.

G. For `dbdomain.DbPassword`, type the password for the database administrator.

H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.

I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

   A. For `source.domainDbType`, type of the database you are currently configured to use. The value for `source.domainDbType` is Derby by default.

   B. For `source.domainDbName`, type the name of the database domain you are currently using.

   C. For `source.domainSchema`, type current schema identifier for objects within the database for this domain.

   D. For `source.domainDataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

   E. For `source.domainDbUrl`, type the url currently used to access your database.

   F. For `source.domainDbUser`, type the name of the user accessing this database.

   G. For `source.domainDbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `oracle.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.

   B. For `oracle.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `oracle.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Creating databases

**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`

3. To create the database users, type the following command:

   ```
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Modifying database properties  
**Next topic:** Creating JCR table spaces

**Related tasks**
Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - &jcrdb is the name of the database you created to store user data.
   - &dbpath is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```
   create tablespace ICMLFQ32 datafile 'dbpath./jcrdb/data/jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile 'dbpath./jcrdb/data/jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile 'dbpath./jcrdb/data/jcrdb._ICMVFP04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile 'dbpath./jcrdb/data/jcrdb._ICMSFQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile 'dbpath./jcrdb/index/jcrdb._ICMLSNDX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
   ```

   A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
   
   B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
   
   C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Setting up databases  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configuring WebSphere Portal to use Oracle RAC
Configuring WebSphere Portal to use Oracle RAC

This section provides information on how to manually transfer data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- Prerequisites
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

Tips:
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following: jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.
- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521)) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME)).
```

- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

Steps for transferring data to another supported database
1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.

2. Enter the following commands to validate configuration properties.
   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password
   ```

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.

4. Stop both WebSphere Application Server and the WebSphere Portal server:
   ```
   ./stopServer.sh server1 -username admin_userid -password admin_password
   ```

5. Transfer the database:
   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root/ConfigEngine`.

   B. Enter the following command:
   ```
   ./ConfigEngine.sh database-transfer -DWasPassword=password
   ```
   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   ```
   ./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response.
   Example: SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);

7. Specify the JDBC URL to connect to the cluster:
   A. Login to the WebSphere Application Server Administrator Console

   B. Navigate to Resources > JDBC Providers

   C. If there is a value in the Node field, remove it and click Apply.

   D. For each Oracle JDBC provider, repeat the following steps:

   1. Click the provider name.
   2. Select Data Sources.
   3. Click the name of the data source.
   4. Under the Oracle data source properties, modify the URL attribute according to Oracle RAC configuration:
   ```
   jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT =1521)) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME= DATABASE_SERVICENAME)))
   ```

   5. Save your changes

8. Change to the directory `wp_profile_root/bin`.

9. Enter the following command to start the WebSphere Portal server:
   ```
   ./startServer.sh WebSphere_Portal
   ```

**Previous topic:** Assigning custom table spaces
Configuring WebSphere Portal to use SQL Server

View information on installing and setting up SQL Server to work with WebSphere Portal.

1. Installing SQL Server
   View the steps to install SQL Server for use with WebSphere Portal.

2. Modifying database properties
   This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

3. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

4. Optional: Assigning custom filegroups
   The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

5. Configuring WebSphere Portal to use SQL Server 2005
   This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing SQL Server

View the steps to install SQL Server for use with WebSphere Portal.

Before you begin this task, complete the following prerequisites:

- You should have completed reviewing the Planning for SQL Server topic.
- You must install SQL Server separately from WebSphere Portal.
- WebSphere Portal requires either the DataDirect Connect for JDBC 3.7 JDBC driver or the Microsoft SQL Server JDBC Driver.
- You can obtain the DataDirect Driver from DataDirect Technologies. The JDBC driver consists of two parts: the JDBC driver libraries and JTA libraries. The JDBC driver libraries must be put on the WebSphere Portal system, while the JTA libraries are intended for SQL Server.
- You can obtain the Microsoft SQL Server JDBC Driver from Microsoft. See the Microsoft SQL Server product documentation for installation details.

The following section provides instructions for installing SQL Server for use with IBM® WebSphere® Application Server and WebSphere Portal. These steps are the same for both the DataDirect and Microsoft drivers unless noted.

1. Install SQL Server and all required patches.
2. Select the authentication mode for this installation:
   - Windows Authentication Mode
   - Mixed Mode (Windows Authentication and SQL Server Authentication)
     Either authentication mode allows the user who is specified as the database administrator in the wkplc_comp.properties file to log in to the SQL server. Mixed Mode authentication allows either a Windows user or a SQL server user, or both, to log in to the SQL Server.
3. In the SQL Server Setup panel, **Components to Install**, select the following components, which are required services for WebSphere Portal:
   - **SQL Server Database Services**
     - **Integration Services** The option **Integration Services**, creates the directory DTS/Binn, where you will need to copy files when you install Microsoft SQL Server JDBC drivers and enable XA connections.
4. Complete the installation using SQL Server documentation as a guide.
5. Enable TCP/IP connectivity in the **SQL Server Configuration Manager**.
6. Install the JDBC driver using one of these methods:
   - Installing DataDirect Connect for JDBC drivers on UNIX
   - Installing DataDirect Connect for JDBC drivers on Windows
   - Installing Microsoft SQL Server JDBC drivers and enabling XA connections
7. Network the connections for MSDTC in the Windows Component Services as described in Microsoft Help and Support.
8. Start SQL Server.

### Installing DataDirect Connect for JDBC drivers on UNIX

1. Purchase and download DataDirect Connect for JDBC and save file 360connectjdbc.jar in a temporary work directory.
2. To create the required files, run the following command from the directory that contains 360connectjdbc.jar:
   
   ```bash
   jar -xvf 360connectjdbc.jar
   ```

3. Run `./Installer.sh` in the same directory.

4. When installation is complete, change directory to `/installation/lib`, where `installation` is the directory in which you installed the DataDirect Connect for JDBC drivers.

5. Run the following command to change the permissions on the JAR files in the `installation/lib` directory:
   ```bash
   chmod 777 *.jar
   ```

6. Change the ownership and group of these files by running the following commands in the `installation/lib` directory:
   ```bash
   chgrp system_grp *.jar
   chown root *.jar
   ```
   Where `system_grp` is the system group as labeled by your operating system.

### Installing Microsoft SQL Server JDBC drivers and enabling XA connections

1. Download and install the Microsoft SQL Server JDBC driver.

2. Copy file `sqljdbc_xa.dll` from the `xa` subdirectory to the `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll` directory of the SQL Server installation.

3. Start the database server.

4. Ensure that the Distributed Transaction Coordinator has been started. The status can be verified in the list of services in the Computer Management console.

5. Start the Microsoft SQL Server Management Studio and connect to the local database engine as the system administrator, `sa`.

6. Select **File > Open > File** and select `xa_install.sql` from the subdirectory of the downloaded and extracted JDBC driver.

7. Execute the script by selecting **Query > Execute**. Note: Any warnings that appear in the messages section of the application window that say that stored procedures cannot be found can be safely ignored.

   
   A. Open the Windows Registry Editor (regedit) and navigate to the element
      
      ```plaintext
      HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XADLL
      ```
   
   B. From the menu bar, select **Edit > New > String Value** to create a new parameter named `sqljdbc_xa.dll` in that element.
   
   C. Change the value of the new parameter to the location of the `sqljdbc_xa.dll` file copied in Step 2 above, for example: `C:\Program Files\Microsoft SQL Server\MSSQL.1\MSSQL\Binn\sqljdbc_xa.dll`

---

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Next topic:** Modifying database properties
Modifying database properties

This section provides information on how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing SQL Server

  The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

  **Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
  - WebSphere Portal 6.1.5 wkplc.properties file reference
  - WebSphere Portal 6.1.5 wkplc_comp.properties file reference
  - WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

- **Working with properties files:**
  - The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:
    - `release.DbName=release`
    - `jcr.DbName=jcrdb`
    - `feedback.DbName=fdbkdb`
    - `likeminds.DbName=lmdb`
    - `community.DbName=commdb`
    - `customization.DbName=custdb`  
  - If you are using a remote database, enter the values for the remote server.
  - Use a forward slash (/) instead of a backslash (\).
  - There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
  - The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
  - Depending on which database domain has to be configured, replace `dbdomain` with:
    - `release`
    - `customization`
    - `community`
    - `jcr`
    - `feedback`
    - `likeminds`
  - The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
    - `dbdomain.DbType`
1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   A. For `dbdomainDbType`, type `sqlserver2005`.
   B. For `dbdomainDbName`, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the `dbdomainDbUrl` property.
   C. For `dbdomainDbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   D. For `dbdomainDataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - `releaseDS`
      - `communityDS`
      - `customizationDS`
      - `jcrDS`
      - `lmdbDS`
      - `feedback`
   E. For `dbdomainDbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:** The database element of this value should match the value of `DbName`.
   F. For `dbdomainDbUser`, type the user ID for the database administrator.
   G. For `dbdomainDbPassword`, type the password for the database administrator.
   H. For `dbdomainDBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.
   I. For `dbdomainDBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.
   J. For `dbdomainDbHome`, type the root location for the database. **Note:** This value is the location to store the database files locally.
   K. For `dbdomainAdminUrl`, type the sqlserver URL without a database attached. This value is used to connect to the server for database administration operations.
   L. For `dbdomainDbHostName`, type the hostname of the database.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are...
set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

A. For source.domainDbType, type of the database you are currently configured to use. The value for source.domainDbType is Derby by default.

B. For source.domainDbName, type the name of the database domain you are currently using.

C. For source.domainDbSchema, type current schema identifier for objects within the database for this domain.

D. For source.domainDataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

E. For source.domainDbUrl, type the url currently used to access your database.

F. For source.domainDbUser, type the name of the user accessing this database.

G. For source.domainDbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_dbtype.properties.

A. For sqlserver2005.DbDriver, type the name of the class that SqlProcessor uses to import SQL files.

B. For sqlserver2005.DbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

C. For sqlserver2005.JdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

D. For sqlserver2005.DbConnectionPoolDataSource, type the name of the implementation class of the connection pool data source.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.

A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

Parent topic: Configuring WebSphere Portal to use SQL Server

Previous topic: Installing SQL Server

Next topic: Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task. As an alternative to automatically setting up the database, you can manually create users and grant privileges.

Before you begin, ensure that the following prerequisites are met:
- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

- Prerequisites
  - Installing SQL Server
  - Modifying database properties

1. Change to the directory `wp_profile_root/ConfigEngine`

2. To create the databases, type the following command:
   ```
   ./ConfigEngine.sh create-database -DWasPassword=password
   ```

3. To create the database users, type the following command:
   ```
   ./ConfigEngine.sh setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal: `\<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Modifying database properties

**Next topic:** Assigning custom filegroups

**Related tasks**

Create users and databases for SQL Server 2005 on AIX and UNIX
Assigning custom filegroups

The repository of WebSphere Portal consists of many tables and indices that are created in default filegroups. When using an existing set of filegroups for the objects of the repository, specify this when executing the database transfer to the target management database system.

Before you begin:

- The custom filegroups must exist prior to the execution of the database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties` file.
- For details on creating filegroups refer to the documentation for the database.

**Prerequisites**

- Installing SQL Server
- Modifying database properties
- Setting up databases

If custom filegroups are assigned, each must be assigned explicitly. The default filegroups can be used to contain database objects; however the name of the default file group must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom filegroups:

1. Determine the names of your custom filegroups.
2. Open the mapping file `wp_profile_root/PortalServer/config/tablespaces` that specifies the table space and index space for each property pair for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.indexspace.indexspace`
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a filespace to each entry in the mapping file. The filegroup name must be prepended by the keyword `ON` and a space. For example: `community.COMP_INST.tablespace=ON COMM8KSPACE`
   Repeat this step for each domain that you are transferring.
4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
   - i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
Configuring WebSphere Portal to use SQL Server 2005

This section provides information on how to manually transfer data to the SQL Server 2005 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to SQL Server 2005.

As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

- **Prerequisites**
  - Installing SQL Server
  - Modifying database properties
  - Setting up databases

Tips:
- If you are transferring from Oracle, the open Cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

Steps for transferring data to another supported database

1. Open a command prompt and change to the directory `wp_profile_root/ConfigEngine`.
2. Enter the following commands to validate configuration properties.
   ```
   ./ConfigEngine.sh validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ./ConfigEngine.sh validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ``
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root/bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:
   ```
   Option                     Description
   WebSphere Application Server ./stopServer.sh server1 -username admin_userid -password admin_password
   WebSphere Portal           ./stopServer.sh WebSphere_Portal -username admin_userid -password admin_password
   ```
5. Transfer the database:
   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.
   A. Change to the directory `wp_profile_root/ConfigEngine`. 

1888
B. Enter the following commands:

```
./ConfigEngine.sh database-transfer -DWaspPassword=password
```

**Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

```
./ConfigEngine.sh database-transfer -DTransferDomainList=jcr -DWaspPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. Change to the directory `wp_profile_root/bin`.

7. Enter the following command to start the WebSphere Portal server:

```
./startServer.sh WebSphere_Portal
```

8. Update the SQL Server 2005 statistics for Portal, and JCR databases by opening SQL Server Management Studio, selecting **New Query**, and running the following query:

```
use db_name
exec sp_updatestats @resample='resample';
```

---

**Parent topic:** Configuring WebSphere Portal to use SQL Server

**Previous topic:** Assigning custom filegroups
Verifying databases

After you configure IBM® WebSphere® Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

- Prerequisites
- [Technotes for database connectivity issues](#)

You can verify the database connection using IBM WebSphere Application Server or by opening WebSphere Portal in a browser.

- To verify that the WebSphere Portal application server is running by using WebSphere Application Server, complete these steps:
  1. Open the WebSphere Application Server administrative console by entering the following address in a browser:
     
     http://hostname.example.com:10027/ibm/console
     
     where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10027 is the default transport port that is created by WebSphere Application Server.
  2. Log into the administrative console.
  3. Depending on your version of WebSphere Application Server, click the appropriate option:
     
     - For WebSphere Application Server Version 6.1: Click Resources & JDBC Providers.
     - For WebSphere Application Server Version 7.0: Click Resources > JDBC > JDBC Providers
  4. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
  5. Select the name of the data source that is defined in wkplc_comp.properties. The default data source is wpdbDS.
  6. Select the name of the JDBC provider that is specified in wkplc_dbtype.properties. The default JDBC provider is wpdbJDBC_dbtype, where dbtype is replaced by the value that matches your environment.
  7. Click Test Connection to verify the database connection. If configuration parameters have been changed, you might need to restart WebSphere Application Server for the test to complete.

- To verify that the WebSphere Portal application server is running by opening WebSphere Portal in a browser, enter the following URL in a supported browser:

  http://hostname.example.com:10040/wps/portal

  where hostname.example.com is the fully qualified host name of the machine where WebSphere Portal is running and 10040 is the default transport port that is created by WebSphere Application Server.

Parent topic: Configure WebSphere Portal to use a remote database
Configuring the primary node to communicate with the deployment manager on Solaris

After installing IBM® WebSphere® Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

- **Prerequisites**
  - Installing WebSphere Portal on Solaris on the primary node
  - Configure WebSphere Portal to use a remote database

Perform the following step to configure WebSphere Portal to communicate with the deployment manager:

Perform the following steps to collect files from the primary node and copy them to the deployment manager:

1. Run the `./ConfigEngine.sh collect-files-for-dmgr -DWasPassword=platformpassword` task, from the `wp_profile_root/ConfigEngine` directory of the primary node, to create an archive or compressed file containing all the files which need to be copied to the Deployment Manager. **Note:** The archive or compressed file will be placed in the `wp_profile_root/filesForDmgr` directory and the file will be called `filesForDmgr.zip`.

2. Stop the deployment manager.

3. Expand the `filesForDmgr.zip` file into the installation root directory of the Deployment Manager; for example in the `/opt/IBM/WebSphere/AppServer` directory. **Note:** If the Deployment Manager profile was not created in the default `AppServer/profiles/Dmgr01` directory, then the `metadata_wkplc.xml` file, located in the `AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml` directory in the zip file, must be placed into the correct Deployment Manager profile directory.

4. If the Deployment Manager profile is running on the same application server where WebSphere Portal is installed, remove the `com.ibm.ws.portletcontainer.deploytask_6.1.5.jar` file from the `AppServer/plugins` directory.

5. Start the deployment manager.

**Parent topic:** Preparing the primary node on Solaris  
**Previous topic:** Configure WebSphere Portal to use a remote database  
**Next topic:** Removing search collections on Solaris

**Related tasks**

- Configuring Portal Search in a cluster on Solaris
Removing search collections on Solaris

If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

- Prerequisites
  - Installing WebSphere Portal on Solaris on the primary node
  - Configure WebSphere Portal to use a remote database
  - Configuring the primary node to communicate with the deployment manager on Solaris

Perform the following step to remove the search collection:

Perform the following steps to delete all existing search collections from the primary node:

1. Log on to WebSphere Portal.
2. Navigate to Administration > Search Administration > Manage Search and then click Search Collections.
3. Click the Delete Collection icon for each search collection and then click OK until they are all deleted.
4. Restart the WebSphere_Portal server and then navigate back to the Search Collections page to verify that all search collections have been deleted.

Parent topic: Preparing the primary node on Solaris
Previous topic: Configuring the primary node to communicate with the deployment manager on Solaris
Choosing the type of cluster to create on Solaris

If you installed a IBM® WebSphere® Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris

Choose one of the following options to create a cluster:

- **Creating a static cluster on Solaris**
  After installing IBM WebSphere Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

- **Creating a new dynamic cluster on Solaris using WebSphere Virtual Enterprise**
  After installing and configuring IBM WebSphere Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

**Parent topic:** Setting up a cluster on Solaris  
**Previous topic:** Preparing the primary node on Solaris  
**Next topic:** Preparing a remote Web server when portal is installed on Solaris
Creating a static cluster on Solaris

After installing IBM® WebSphere® Portal on the primary node, configuring a remote database, and preparing the primary node to communicate with the Deployment Manager, you can create your static cluster to handle failover requests.

Perform the following steps to create the cluster:

1. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the \wp_profile_root\ConfigEngine\properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.

   **Important:** Ensure that you set **WasUserid** and **WasPassword** to the Deployment Manager user ID and password.

2. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the \wp_profile_root\ConfigEngine\properties directory:

   **Note:** Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.

   A. Set **WasSoapPort** to the port used to connect remotely to the deployment manager.
   B. Set **WasRemoteHostName** to the full host name of the server used to remotely connect to the deployment manager.
   C. Verify that **WasPassword** is set to your deployment manager password.
   D. Verify that **PortalAdminPwd** is set to your WebSphere Portal password.
   E. Verify that **ClusterName** is set.
   F. Verify that **PrimaryNode** is set to **true**.

3. Make a backup copy of the \wp_profile_root\config\cells\cell_name\wim\config\wimconfig.xml and \wp_profile_root\config\cells\cell_name\wim\model\wimxmlextension.xml, if available, files.

4. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the \wp_profile_root\ConfigEngine directory of the primary node.

   **Note:** If you want to specify custom ports for the nodeagent, add the -DPortPropsFile=full to portsfile parameter to the cluster-node-config-pre-federation task. You can use the ports files that are found on the Setup CD for WebSphere_Portal and server1 as a guide.

   **Note:** You may receive a message about accepting an SSL signer certificate. Failure to accept the SSL signer certificate will cause the script to fail. Alternatively, the com.ibm.ssl.enableSignerExchangePrompt flag can be enabled in the ssl.client.props file for "DefaultSSLSessions" in order to allow acceptance of the signer during the connection attempt.

   **Warning:** If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:

   A. Remove the node if the AddNode task succeeded.
   B. Log on to the deployment manager and perform the following steps if the items exist:
      1. Remove all enterprise applications.
      2. Remove the WebSphere_Portal server definition.
      3. Remove the WebSphere Portal JDBC Provider.

   **Note:** If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following technote: Migrating with Lookaside Data.
Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:

**Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.

A. Set the property value for `federated.dbDbType` if using a database user registry or set the property value for `laDbType` if using a property extension database in the `wkplc.properties` file.

**Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.dbDbType` to the same value that is in the `wkplc.properties` file on the primary node.

B. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWassPassword=dmgr_password -DDBDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root`/ConfigEngine directory to create the variable used to access the VMM database jars.

**Note:** The `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

C. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWassPassword=dmgr_password` task.

Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWassPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root`/ConfigEngine directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Attention:** The password value for `-DWassPassword` is the Deployment Manager administrative password.

**Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWassPassword=dmgr_password` task.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

D. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup -DWassPassword=dmgr_password` task.

Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options:

- Configuring a Web server and an application server on separate machines (remote)
- Configuring a Web server and an application server profile on the same machine
- Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard.

E. Perform the following steps to access the Web Content Management content through an external Web server:

A. Log on to the deployment manager administrative console.
B. Select Environment > WebSphere Variables.
C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select System Administration > Nodes.
   2. Select the node that you want to synchronize from the list.
   3. Click Full Resynchronize.
G. Log off of the deployment manager administrative console.

11. Run the following tasks to propagate your changes: Note: WebSphere_Portal_nodename is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the serverstatus -all task to get a list of the server names and their status.
A. ./stopManager.sh -username admin_userid -password admin_password, from the dmgr_profile_root\bin directory
B. ./stopNode.sh -username admin_userid -password admin_password, from the wp_profile_root/bin directory
C. ./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password
D. ./startManager.sh, from the dmgr_profile_root\bin directory
E. ./startNode.sh, from the wp_profile_root/bin directory
F. ./startServer.sh WebSphere_Portal_nodename

12. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information:

- Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Creating a new dynamic cluster on Solaris using WebSphere Virtual Enterprise

After installing and configuring IBM® WebSphere® Portal on your primary node and all additional nodes, you can create a new dynamic cluster. A dynamic cluster monitors performance and load information and is able to dynamically create and remove cluster members based on the workload.

Before creating your dynamic cluster, install and configure the Deployment Manager and perform all the tasks under “Preparing the primary node.” On the Deployment Manager system, install WebSphere Virtual Enterprise and augment the deployment manager profile. On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- Prerequisites
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
    - Augmenting profiles

Perform the following steps to create a dynamic cluster:

1. Perform the following steps for on the primary node of the dynamic cluster:
   A. Prepare the node for the dynamic cluster; perform all tasks under Preparing the primary node.
   B. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading.
   C. Stop the server1 and WebSphere_Portal servers on the primary node and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
      1. Set WasSoapPort to the port used to connect remotely to the deployment manager.
      2. Set WasRemoteHostName to the full host name of the server used to remotely connect to the deployment manager.
      3. Verify that WasPassword is set to your deployment manager password.
      4. Verify that PortalAdminPwd is set to your WebSphere Portal password.
      5. Verify that ClusterName is set.
      6. Verify that PrimaryNode is set to true.
   D. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password task, from the wp_profile_root/ConfigEngine directory of the primary node.

   Warning: If the cluster-node-config-pre-federation fails for any reason, you must perform the following steps before rerunning the task:
      1. Remove the node if the AddNode task succeeded.
      2. Log on to the deployment manager and perform the following steps if the items exist:
         A. Remove all enterprise applications.
         B. Remove the WebSphere_Portal server definition.
         C. Remove the WebSphere Portal JDBC Provider.

Note: If you are migrating from a version prior to Version 6.1.0 that contains Lookaside data, read the following
E. Run the following task. Include each node name as a comma separated list in the command:

1. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file. **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDomainName=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars. **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

F. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password task`.

G. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

**Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-dynamic-cluster-setup` task completes.

After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

**Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

2. Log on to the deployment manager administrative console.

3. Perform the following steps to create a node group:
   A. Click **System administration** > **Node groups**.
   B. Click **New**.
   C. Type the node group **Name**.
   D. Optional: Type any information about the node group in the **Description** text box.
   E. Click **OK**.
   F. Click the **Save** link to save your changes to the master configuration.

4. Perform the following steps to add members to the node group:
   A. Click **System administration** > **Node groups**.
   B. Click on the name of the node group that you want to add members to.
   C. Click **Node group members** under Additional Properties.
   D. Click **Add**.
   E. Select the primary node and then click **Add**.
   F. Click the **Save** link to save your changes to the master configuration.

5. Perform the following steps to create a dynamic cluster in the node group:
   A. Click **Servers** > **Dynamic clusters**.
   B. Click **New**.
C. Select WebSphere Application Server from the **Server Type** pull-down menu and then click **Next**.

D. Type the cluster name in the **Dynamic cluster name** text box and then click **Next**. Type the same value that you provided for the **ClusterName** parameter in the wkplc.properties file of your primary node.

E. Remove all default membership policies and then click **Subexpression builder**.

F. Enter the following information in the Subexpression builder window:

1. Select **AND** from the **Logical operator** pull-down menu.
2. Select **Nodegroup** from the **Select operand** pull-down menu.
3. Select **Equals (=)** from the **Operator** pull-down menu.
4. Type the nodegroup name you created in the previous step in the **Value** text box.
5. Click **Generate subexpression**.
6. Click **Append**.

G. Click **Preview membership** to verify that all nodes included in the nodegroup display and then click **Next**.

H. Click the **Create the cluster member using an existing server as a template** radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu.

I. Click **Next**.

J. Specify the dynamic cluster properties and then click **Next**.

K. Review the summary page to verify your actions and then click **Finish**.

L. Click the **Save** link to save your changes to the master configuration.

6. Define or verify the following parameters in the wkplc.properties file, located in the `wp_profile_root`/ConfigEngine/properties directory:

   A. Set **ClusterName** to the name of the new dynamic cluster.
   
   B. Verify that **CellName** is set to the deployment manager cell.
   
   C. Verify that **NodeName** is set to the local WebSphere Portal node.
   
   D. Set **ServerName** to the server that will be used for the dynamic cluster member on this node.

   **Note:** Log on to the deployment manager administrative console and click Dynamic Clusters > PortalCluster > Dynamic cluster members to find the name of the server used for the dynamic cluster.

E. Verify that **PrimaryNode** is set to true.

7. Run the `./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password` task from the `wp_profile_root`/ConfigEngine directory to create the dynamic cluster.

   **Note:** This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

8. Perform the following steps to access the Web Content Management content through an external Web server:

   A. Log on to the deployment manager administrative console.
   
   B. Select Environment > WebSphere Variables.
   
   C. From the *Scope* drop-down menu, select the Node-nodename, Server-servername option to narrow the scope of the listed variables, where Node-nodename is the node that contains the application server.
   
   D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   
   E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   
   F. Perform the following steps to synchronize the node with the deployment manager:

   1. Select System Administration > Nodes.
   
   2. Select the node that you want to synchronize from the list.
   
   3. Click Full Resynchronize.
   
   G. Log off of the deployment manager administrative console.

9. Run the following tasks to propagate your changes: **Note:** WebSphere_Portal_nodename is the name of the node's WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the
server name, run the serverstatus -all task to get a list of the server names and their status.

A. `./stopManager.sh -username admin_userid -password admin_password`, from the dmgr_profile_root/bin directory
B. `./stopNode.sh -username admin_userid -password admin_password`, from the wp_profile_root/bin directory
C. `./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`
D. `./startManager.sh`, from the dmgr_profile_root/bin directory
E. `./startNode.sh`, from the wp_profile_root/bin directory
F. `./startServer.sh WebSphere_Portal_nodename`

Parent topic: Choosing the type of cluster to create on Solaris
Preparing a remote Web server when portal is installed on Solaris

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- **Prerequisites**
  - Preparing the WebSphere Application Server Deployment Manager on Solaris
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.
2. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.
3. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `On`; the directive should be added at the root level as a global directive.
4. Stop the Web server.
5. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to Selecting a Web server topology diagram and roadmap for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to Configuring a Web server for a non-default profile.

   If using WebDAV: After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

   **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see Common questions about the Web server plug-in.
6. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.
7. Start the Web server.

**Parent topic:** Preparing prerequisite and corequisite software on Solaris

**Previous topic:** Preparing the WebSphere Application Server Deployment Manager on Solaris

**Parent topic:** Setting up a cluster on Solaris

**Previous topic:** Choosing the type of cluster to create on Solaris

**Next topic:** Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment
Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment

Configure user registry security on IBM® WebSphere® Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

Prior to configuring security, you should use the IBM WebSphere Application Server backupConfig task to create and store a backup of the IBM WebSphere Portal configuration; see backupConfig command for information.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris

Perform the following tasks to configure WebSphere Portal to use a user registry:

1. **Preparing user registries on Solaris**
   Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

2. **Choosing your user registry model on Solaris in a clustered environment**
   Choose between securing IBM WebSphere Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.
Preparing user registries on Solaris

Install and setup an LDAP server as a user registry to store user information and authenticate users in your high availability production environment.

Choose the appropriate LDAP server to install and setup:

- **Preparing a Domino Directory server**
  If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a SecureWay Security Server**
  If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Novell eDirectory**
  If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Sun Java System Directory Server**
  If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

- **Preparing a Tivoli Directory Server**
  If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM WebSphere Portal.

**Parent topic:** Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment  
**Next topic:** Choosing your user registry model on Solaris in a clustered environment
Preparing a Domino Directory server

If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Domino Directory:

1. Perform the following steps to install the Domino Directory:
   A. Go to Lotus Domino documentation.
   B. Select the appropriate version tab for your product.
   C. Click the Download/View online link for the Lotus Domino for multiple platforms Information Center.
   D. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > Server installation > Installing Domino on Unix and perform this task.
   E. Click Domino Administrator Help > Installation > Installing and setting up Domino servers > The Domino server setup program and perform this task.

2. Perform the following steps as a guide to create the WebSphere Portal administrative user:
   A. Navigate to the People view of the Domino Directory and then click Add Person.
   B. Enter the following values in the New Person form to create the wpsbind user:
      - Last Name
        - wpsbind
      - User Name
        - wpsbind/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - wpsbind Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsbind
      - Internet password
        - wpsbind
   C. Click Save and Close to save the new person record for wpsbind and return to the People view.
   D. Click Add Person and enter the following values in the New Person form to create the wpsadmin user:
      - Last Name
        - wpsadmin, where wpsadmin in the user ID for the WebSphere Portal Administrator
      - User Name
        - wpsadmin/DominoDomain, where DominoDomain is your Lotus Domino Internet domain
        - wpsadmin Note: Make sure you enter two values in the User Name field, where the first value includes the Lotus Domino domain.
      - Short name/UserID
        - wpsadmin
      - Internet password
        - wpsadmin
   E. Click Save and Close to save the new person record for wpsadmin and return to the People view.
   F. Navigate to the Groups view and click Add Group.
   G. Enter the following values in the New Group form on the Basic tab:
      - Group name
- wpsadmins

**Note:** If you plan to configure WebSphere Portal for multiple user registries and your Lotus Domino LDAP will share a realm with another user registry, you must use the hierarchical naming convention for the group names, for example: wpsadmins/DominoDomain, to avoid unexpected results during WebSphere Portal runtime.

- **Group type**
  - Multi-purpose

- **Members**
  - wpsbind/DominoDomain
  - wpsadmin/DominoDomain

**Note:** You can add additional administrator users if required.

H. **Click Save and Close** to save the wpsadmins group with the wpsbind and wpsadmin users as members.

3. Perform the following steps to update the access control list for the Domino Directory:
   
   A. Open the names.nsf file in the Lotus Domino Administrator or Lotus Notes client.
   
   B. **Click File > Application > Access Control** from the main menu to open the access control list for the file.
   
   C. In the **Access Control List > Basics** panel, ensure that the wpsadmins group has either Author or Editor access.
   
   D. Add the following Role Types to the wpsadmins group:
      
      - GroupCreator
      - GroupModifier
      - UserCreator
      - UserModifier
   
   E. **Click OK.**

**Parent topic:** Preparing user registries on Solaris
Preparing a SecureWay Security Server

If you plan to use a SecureWay Security Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare SecureWay Security Server:

1. Install SecureWay Security Server; refer to the IBM SecureWay™ Security Server for z/OS® and OS/390® for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.

   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.

   C. Replace every dc=yourco,dc=com with your suffix.

   D. Replace any prefixes and suffixes that are unique to your LDAP server.

   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.

   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.

   G. Save your changes.

   H. Follow the instructions provided with your directory server to import the LDIF file.

   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on Solaris
Preparing a Novell eDirectory

If you plan to use a Novell eDirectory as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Novell eDirectory:

1. Install Novell eDirectory; refer to eDirectory for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on Solaris
Preparing a Sun Java System Directory Server

If you plan to use a Sun Java System Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Sun Java System Directory Server:

1. Install Sun Java System Directory Server; refer to Oracle software for information.

2. Perform the following steps to create the WebSphere Portal administrative user:
   A. Optional: Perform the following steps to create a new directory suffix:
      1. Click the Server Administration folder, located in the left-hand navigation of the directory server console.
      2. Click the Manage Server Properties folder under the Server Administration folder and then select Suffixes on the main page.
      3. Type the Base DN name for the suffix; for example: dc=yourcompany,dc=com.
      4. Click Add.
      5. Click OK to save your changes.
      6. Stop and restart the LDAP server.
   B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
      - Use the PortalUsers.ldif file as a working example and adapted appropriately to work with your LDAP server.
      - Use the ContentUsers.ldif file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   C. Replace every dc=yourco,dc=com with your suffix.
   D. Replace any prefixes and suffixes that are unique to your LDAP server.
   E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the objectclasses to accessGroup. If using Tivoli Access Manager Version 6, set the objectclasses to groupOfNames.
   G. Save your changes.
   H. Follow the instructions provided with your directory server to import the LDIF file.
   I. Stop and restart the LDAP server.

Parent topic: Preparing user registries on Solaris
Preparing a Tivoli Directory Server

If you plan to use a Tivoli Directory Server as an LDAP user registry, you must install and set up the server so that it will communicate with IBM® WebSphere® Portal.

Perform the following steps to prepare Tivoli Directory Server:

   - **Note:** Due to a restriction in Tivoli Directory Server, users or groups must not contain a Turkish uppercase dotted I or lowercase dotted i in the DN as this will prevent correct retrieval of that user or group.

2. Perform the following steps to create the WebSphere Portal administrative user:
   - A. Optional: Perform the following steps to create a new directory suffix:
     1. Click the **Server Administration** folder, located in the left-hand navigation of the directory server console.
     2. Click the **Manage Server Properties** folder under the Server Administration folder and then select **Suffixes** on the main page.
     3. Type the **Base DN** name for the suffix; for example: `dc=yourcompany,dc=com`.
     4. Click **Add**.
     5. Click **OK** to save your changes.
     6. Stop and restart the LDAP server.
   - B. Open the appropriate LDIF file, located in the root directory of the CD setup, with a text editor:
     - Use the `PortalUsers.ldif` file as a working example and adapted appropriately to work with your LDAP server.
     - Use the `ContentUsers.ldif` file for the IBM DB2® Content Manager group and user IDs if you configured DB2 Content Manager.
   - C. Replace every `dc=yourco,dc=com` with your suffix.
   - D. Replace any prefixes and suffixes that are unique to your LDAP server.
   - E. You can specify user names other than wpsadmin and wpsbind. For security reasons, specify nontrivial passwords for these administrator accounts.
   - F. Optional: If using IBM Tivoli® Access Manager Version 5.1, set the **objectclasses** to **accessGroup**. If using Tivoli Access Manager Version 6, set the **objectclasses** to **groupOfNames**.
   - G. Save your changes.
   - H. Follow the instructions provided with your directory server to import the LDIF file.
   - I. Stop and restart the LDAP server.

---

**Parent topic:** Preparing user registries on Solaris
Choosing your user registry model on Solaris in a clustered environment

Choose between securing IBM® WebSphere® Portal with a standalone LDAP user registry or by adding LDAP user registries and/or database user registries to the default federated repository.

Choose one of the following user registry models:

- **Configuring a stand-alone LDAP user registry on Solaris in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Configuring the default federated repository on Solaris in a clustered environment**
  Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

- **Adapting the attribute configuration**
  After installing IBM WebSphere Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

**Parent topic:** Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment

**Previous topic:** Preparing user registries on Solaris
Configuring a stand-alone LDAP user registry on Solaris in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

Choose one of the following options to configure your LDAP server:

- **Configuring a stand-alone LDAP user registry on Solaris in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry to store all user account information for authorization.

- **Configuring a stand-alone LDAP user registry over SSL on Solaris in a clustered environment**
  Configure IBM WebSphere Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

**Parent topic:** Choosing your user registry model on Solaris in a clustered environment
Configuring a stand-alone LDAP user registry on Solaris in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry to store all user account information for authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps. If you need to rerun the wp-modify-ldap-security task to change the LDAP repositories or because the task failed, you must choose a new name for the realm using the standalone.ldap.realm parameter or you can set ignoreDuplicateIDs=true in the wkplc.properties file, before rerunning the task.

Perform the following steps to configure a standalone LDAP user registry:

Note: Use the wp_security_xxx.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_xxx.properties helper file.

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Standalone LDAP configuration heading:

   - standalone.ldap.id
   - standalone.ldap.host
   - standalone.ldap.port
   - standalone.ldap.bindDN
   - standalone.ldap.bindPassword
   - standalone.ldap.ldapServerType
   - standalone.ldap.userIdMap
   - standalone.ldap.groupIdMap
   - standalone.ldap.groupMemberIdMap
   - standalone.ldap.userFilter
   - standalone.ldap.groupFilter
   - standalone.ldap.serverId
   - standalone.ldap.serverPassword
   - standalone.ldap.realm
   - standalone.ldap.primaryAdminId
   - standalone.ldap.primaryAdminPassword
   - standalone.ldap.primaryPortalAdminId
   - standalone.ldap.primaryPortalAdminPassword
   - standalone.ldap.primaryPortalAdminGroup
   - standalone.ldap.baseDN
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.et.group.objectClasses`
   - `standalone.idap.et.group.objectClassesForCreate`
   - `standalone.idap.et.group.searchBases`
   - `standalone.idap.et.personaccount.objectClasses`
   - `standalone.idap.et.personaccount.objectClassesForCreate`
   - `standalone.idap.et.personaccount.searchBases`

4. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.gm.groupMemberName`
   - `standalone.idap.gm.objectClass`
   - `standalone.idap.gm.scope`
   - `standalone.idap.gm.dummyMember`

5. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.idap.personAccountParent`
   - `standalone.idap.groupParent`
   - `standalone.idap.personAccountRdnProperties`
   - `standalone.idap.groupRdnProperties`

6. Save your changes to the `wkplc.properties` file.

7. Optional: Enter the following Web content authors parameters in the `wkplc_comp.properties` file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. **Note:** See the `wkplc_comp.properties` file for specific information about the required parameters and for advanced parameters.
   - `WcmContentAuthorsGroupId`
   - `WcmContentAuthorsGroupCN`

8. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, **WasPassword** is the value entered during installation and not a value found in your LDAP user registry. **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

9. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set the stand-alone LDAP user registry.

10. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

11. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

12. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the
LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root` file:

```
/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties
```

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured: *Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management*

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

13. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

Configuring a stand-alone LDAP user registry over SSL on Solaris in a clustered environment

Configure IBM® WebSphere® Portal to use a standalone LDAP user registry over SSL to store all user account information for secure authorization.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to configure a standalone LDAP user registry over SSL:

Note: Use the wp_security_XXX.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_security_XXX.properties helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:

   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to Security > SSL certificate and key management > SSL configurations.
        3. Click the appropriate SSL configuration from the list. For example,
           - Stand-alone environments: NodeDefaultSSLSettings
           - Clustered environments: CellDefaultSSLSettings

           **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.

        4. Click Key stores and certificates.
        5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
        6. Click Signer certificates, click Add, and then enter the following information:
           - Type the Alias the key store uses for the signer certificate.
           - Type the File name where the signer certificate is located.
        7. Click OK and then click Save to save the changes to the master configuration.

   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
      2. Navigate to Security > SSL certificate and key management > SSL configurations.
      3. Click the appropriate SSL configuration from the list. For example,
         - Stand-alone environments: NodeDefaultSSLSettings

1916
- Clustered environments: **CellDefaultSSLSettings**

Clustered environments: Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.

4. Click **Key stores and certificates**.

5. Click the appropriate trust store from the list; for example, **NodeDefaultTrustStore**.

6. Click **Signer certificates**, click **Retrieve from port**, and then enter the following information:
   - Type the **Host** name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the **Port** used when attempting to retrieve the signer certificate.
   - Type the **Alias** the key store uses for the signer certificate.

7. Click **Retrieve signer information** to retrieve the certificate from the port.

8. Click **OK** and then click **Save** to save the changes to the master configuration.

- **Client trust store**

  **Note**: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

  A. See Secure installation for client signer retrieval.

  B. Run the **retrieveSigners** task from the **wp_profile_root/bin** directory; see **retrieveSigners command** for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. **Note**: This task might report an error, but it does successfully update the trust store. You can ignore the error message.

  C. Update the trust store properties file:

    1. Use a text editor to open the **ssl.client.props** file, located in the **wp_profile_root/properties** directory.
    2. Change the **com.ibm.ssl.trustStore** parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter
       
       ```
       com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12
       ```
       
       to use the default trust store.
    3. Save your changes.

  2. Use a text editor to open the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory.

  3. Required: Enter a value for the following required parameters in the **wkplc.properties** file under the VMM Standalone LDAP configuration heading. **Note**: See the properties file for specific information about the required parameters and for advanced parameters.

    - **standalone.idap.ld**
    - **standalone.idap.host**
    - **standalone.idap.port**
    - **standalone.idap.blIndDN**
    - **standalone.idap.bindPassword**
    - **standalone.idap.idapServerType**
    - **standalone.idap.userIdMap**
    - **standalone.idap.groupIdMap**
    - **standalone.idap.groupMemberIdMap**
    - **standalone.idap.userFilter**
    - **standalone.idap.groupFilter**
    - **standalone.idap.serverId**
    - **standalone.idap.serverIdPassword**
    - **standalone.idap.realm**
    - **standalone.idap.primaryAdminId**
    - **standalone.idap.primaryAdminPassword**
    - **standalone.idap.primaryPortalAdminId**
4. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.et.group.objectClasses`
   - `standalone.ldap.et.group.objectClassesForCreate`
   - `standalone.ldap.et.group.searchBases`
   - `standalone.ldap.et.personaccount.objectClasses`
   - `standalone.ldap.et.personaccount.objectClassesForCreate`
   - `standalone.ldap.et.personaccount.searchBases`

5. Required: Enter a value for the following required group member parameters in the `wkplc.properties` file under the Group member attributes heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.gm.groupMemberName`
   - `standalone.ldap.gm.objectClass`
   - `standalone.ldap.gm.scope`
   - `standalone.ldap.gm.dummyMember`

6. Required: Enter a value for the following required relative distinguished name (RDN®) parameters in the `wkplc.properties` file under the Default parent, RDN attribute heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `standalone.ldap.personAccountParent`
   - `standalone.ldap.groupParent`
   - `standalone.ldap.personAccountRdnProperties`
   - `standalone.ldap.groupRdnProperties`

7. Enter a value for the following parameters to enable Secure Socket Layers (SSL): **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   Required parameters:
   - `standalone.ldap.sslEnabled`
   - `standalone.ldap.sslConfiguration`

   Optional parameters:
   - `standalone.ldap.certificateMapMode`
   - `standalone.ldap.certificateFilter`

8. Save your changes to the `wkplc.properties` file.

9. Run the `./ConfigEngine.sh validate-standalone-ldap -DWasPassword=password` task to validate your LDAP server settings. **Attention:** If you have not deleted the default file repository, `WasPassword` is the value entered during installation and not a value found in your LDAP user registry. **Note:** During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press `y` then `Enter`.

10. Run the `./ConfigEngine.sh wp-modify-ldap-security -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to set the stand-alone LDAP user registry.

11. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

12. Run the `./ConfigEngine.sh wp-validate-standalone-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured
LDAP user registry.**Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a stand-alone LDAP user registry on Solaris in a clustered environment

**Related tasks**
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Configuring the default federated repository on Solaris in a clustered environment

Add an LDAP user registry and/or a database user registry to the default federated repository to create seamless authentication within the repository.

Perform the following tasks to add user registries to the default federated repository:

- **Configuring a federated LDAP user registry on Solaris in a clustered environment**
  Depending on the type of data that is exchanged between IBM WebSphere Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal.

- **Adding a database user registry on Solaris in a clustered environment**
  Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

- **Adding realm support on Solaris in a clustered environment**
  A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

**Parent topic:** Choosing your user registry model on Solaris in a clustered environment
Configuring a federated LDAP user registry on Solaris in a clustered environment

Depending on the type of data that is exchanged between IBM® WebSphere® Application Server, IBM WebSphere Portal, and your LDAP server, you can either configure your LDAP server over SSL or configure it to have direct access to IBM WebSphere Application Server and IBM WebSphere Portal. Choose one of the following options to configure your LDAP server:

- **Adding an LDAP user registry on Solaris in a clustered environment**
  Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName, o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

- **Adding an LDAP user registry over SSL on Solaris in a clustered environment**
  Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

**Parent topic:** Configuring the default federated repository on Solaris in a clustered environment
Adding an LDAP user registry on Solaris in a clustered environment

Add an LDAP user registry to the default federated repository to store user account information for authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time. If IBM® Lotus® Domino® will be one of your user registries in a multiple registry configuration and will share a realm with another user registry, ensure that the groups are stored in a hierarchical format in the Domino Directory as opposed to the default flat-naming structure. For example, the flat-naming convention is `cn=groupName` and the hierarchical format is `cn=groupName, o=root`. You must also ensure that the IDs that are unique between the default federated repository and the LDAP you are adding. For example, if the default federated repository contains an ID such as `wpsadmin`, this ID cannot exist in the LDAP you are adding.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip:** Perform these steps on the primary node only.

**Note:** Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
2. Required: Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `federated.ldap.id`
   - `federated.ldap.host`
   - `federated.ldap.port`
   - `federated.ldap.bindDN`
   - `federated.ldap.bindPassword`
   - `federated.ldap.ldapServerType`
   - `federated.ldap.baseDN`
3. Required: Enter a value for the following required entity types parameters in the `wkplc.properties` file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - `federated.ldap.et.group.objectClasses`
   - `federated.ldap.et.group.objectClassesForCreate`
   - `federated.ldap.et.group.searchBases`
   - `federated.ldap.et.personaccount.objectClasses`
4. Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attribute heading: 
   Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - federated.ldap.et.personaccount.objectClassesForCreate
   - federated.ldap.et.personaccount.searchBases

5. Save your changes to the wkplc.properties file.

6. Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product. Note: See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.
   - WcmContentAuthorsGroupId
   - WcmContentAuthorsGroupCN

7. Run the ./ConfigEngine.sh validate-federated-ldap -DWasPassword=password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry.
   Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

8. Run the ./ConfigEngine.sh wp-create-ldap -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add an LDAP user registry to the default federated repository. Note: Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

10. Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
    A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
    B. Enter a value for the following required parameters in the wkplc.properties file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:
       Note: See the properties file for specific information about the required parameters and for advanced parameters.
       - id
       - baseDN
       - nameInRepository
    C. Save your changes to the wkplc.properties file.
    D. Run the ./ConfigEngine.sh wp-create-base-entry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to create a base entry in a repository.
    E. Stop and restart all necessary servers to propagate your changes.

11. Optional: Run the ./ConfigEngine.sh wp-query-repository -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to list the names and types of configured repositories.

12. Run the ./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to check that all defined attributes are available in the configured
LDAP user registry. **Important:** When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

13. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

14. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

   E. Stop and restart all necessary servers to propagate your changes.

15. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

    **Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

    A. Edit the `wp_profile_root` `/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties` file.

    B. Add the following lines to the file:

    ```
    ccn=contentauthors, o=defaultWIMFileBasedRealm -> content_authors_group_DN
    ```
Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `.ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password task`, located in the `wp_profile_root/ConfigEngine` directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured. Table 1. Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone.ldap.realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated.realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated.realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

16. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

17. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

   **Important:**
   - Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
   - Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

   **Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root/ConfigEngine` directory: `.ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.

B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine` directory: `.ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
18. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it.

The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

Adding an LDAP user registry over SSL on Solaris in a clustered environment

Add an LDAP user registry over SSL to the default federated repository to store user account information for secure authorization. You can add multiple LDAP user registries to the default federated repository although you can only add one LDAP server at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add an LDAP user registry over SSL to the default federated repository; you must repeat these steps for each additional LDAP user registry that you plan to add:

**Tip**: Perform these steps on the primary node only.

**Note**: Use the `wp_add_federated_xxx.properties` helper file, located in the `wp_profile_root/ConfigEngine/config/helpers` directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the `wkplc.properties` file, you will use your `wp_add_federated_xxx.properties` helper file.

1. To specify the LDAP server's SSL certificate in the default client trust store, perform either the steps for the server trust store or the client trust store:
   - **Server trust store**
     A. Add the certificate to the trust store:
        1. Log in to the WebSphere Application Server Administrative Console.
        2. Navigate to **Security > SSL certificate and key management > SSL configurations**.
        3. Click the appropriate SSL configuration from the list. For example,
           - **Stand-alone environments**: `NodeDefaultSSLSettings`
           - **Clustered environments**: `CellDefaultSSLSettings`
        
           **Clustered environments**: Ensure the setting for **SSL configuration for outbound connection** matches your SSL settings.
        4. Click **Key stores and certificates**.
        5. Click the appropriate trust store from the list; for example, `NodeDefaultTrustStore`.
        6. Click **Signer certificates**, click **Add**, and then enter the following information:
           - Type the **Alias** the key store uses for the signer certificate.
           - Type the **File name** where the signer certificate is located.
        7. Click **OK** and then click **Save** to save the changes to the master configuration.
   B. Retrieve the certificate from the port:
      1. Log in to the WebSphere Application Server Administrative Console.
2. Navigate to Security > SSL certificate and key management > SSL configurations.
3. Click the appropriate SSL configuration from the list. For example,
   - Stand-alone environments: NodeDefaultSSLSettings
   - Clustered environments: CellDefaultSSLSettings
   **Clustered environments:** Ensure the setting for SSL configuration for outbound connection matches your SSL settings.
4. Click Key stores and certificates.
5. Click the appropriate trust store from the list; for example, NodeDefaultTrustStore.
6. Click Signer certificates, click Retrieve from port, and then enter the following information:
   - Type the Host name used when attempting to retrieve the signer certificate from the SSL port.
   - Type the SSL Port used when attempting to retrieve the signer certificate.
   - Type the Alias the key store uses for the signer certificate.
7. Click Retrieve signer information to retrieve the certificate from the port.
8. Click OK and then click Save to save the changes to the master configuration.
   **Client trust store** Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.
A. See Secure installation for client signer retrieval.
B. Run the retrieveSigners task from the wp_profile_root/bin directory; see retrieveSigners command for information. In a deployed environment, you will need to run the retrieveSigners task, for any federated node, against the Deployment Manager. Note: This task might report an error, but it does successfully update the trust store. You can ignore the error message.
C. Update the trust store properties file:
   1. Use a text editor to open the ssl.client.props file, located in the wp_profile_root/properties directory.
   2. Change the com.ibm.ssl.trustStore parameter and the related trust store parameters to match the trust file specified in the SSL configuration. For example, enter com.ibm.ssl.trustStore=${CONFIG_ROOT}\cells\wpsbvt\nodes\wpsbvt\trust.p12 to use the default trust store.
   3. Save your changes.
2. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
3. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM Federated LDAP Properties heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - federated.idp.id
   - federated.idp.host
   - federated.idp.port
   - federated.idp.bindDN
   - federated.idp.bindPassword
   - federated.idp.idpServerType
   - federated.idp.baseDN
4. Required: Enter a value for the following required entity types parameters in the wkplc.properties file under the LDAP entity types heading: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.
   - federated.idp.et.group.objectClasses
   - federated.idp.et.group.objectClassesForCreate
   - federated.idp.et.group.searchBases
Required: Enter a value for the following required group member parameters in the wkplc.properties file under the Group member attribute heading:Note: See the properties file for specific information about the required parameters and for advanced parameters.
- federated.idap.gm.groupMemberName
- federated.idap.gm.objectClass
- federated.idap.gm.scope
- federated.idap.gm.dummyMember

Enter a value for the following parameters to enable Secure Socket Layers (SSL):Note: See the properties file for specific information about the required parameters and for advanced parameters.
Required parameters:
- federated.idap.sslEnabled
- federated.idap.sslConfiguration

Optional parameters:
- federated.idap.certificateMapMode
- federated.idap.certificateFilter

Save your changes to the wkplc.properties file.

Optional: Enter the following Web content authors parameters in the wkplc_comp.properties file under the Web Content Management attribute heading and then save your changes. This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates provided with the product.Note: See the wkplc_comp.properties file for specific information about the required parameters and for advanced parameters.
- WcmContentAuthorsGroupId
- WcmContentAuthorsGroupCN

Run the ./ConfigEngine.sh validate-federated-ldap -DWasPassword=password task to validate your LDAP server settings. Attention: If you have not deleted the default file repository, WasPassword is the value entered during installation and not a value found in your LDAP user registry.

Note: During the validation task, you may receive the following prompt: Add signer to the trust store now?. Press y then Enter.

Run the ./ConfigEngine.sh wp-create-ldap -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add an LDAP user registry to the default federated repository. Note: Users who are not in an LDAP do not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

Optional: Perform the following steps to create additional base entries within the LDAP user registry; repeat these steps for each base entry that you want to create for multiple realm support:
A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

B. Enter a value for the following required parameters in the wkplc.properties file under the VMM repository base entry configuration heading to create additional base entries within the LDAP user registry to use when creating realms:

Note: See the properties file for specific information about the required parameters and for advanced parameters.
C. Save your changes to the wkplc.properties file.

D. Run the `./ConfigEngine.sh wp-create-base-entry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to create a base entry in a repository.

E. Stop and restart all necessary servers to propagate your changes.

13. Optional: Run the `./ConfigEngine.sh wp-query-repository -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the names and types of configured repositories.

14. Run the `./ConfigEngine.sh wp-validate-federated-ldap-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to check that all defined attributes are available in the configured LDAP user registry. Important: When you finish configuring your LDAP user registry, see "Adapting the attribute configuration" for information about adding and mapping attributes to ensure proper communication between WebSphere Portal and the LDAP server.

15. Perform the following steps to update the user registry where new users and groups are stored:

   **Note:** If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   **Attention:** During installation, the default file repository creates a default value in the `personAccountRdnProperties` and `groupRdnProperties` parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM supported entity types configuration heading:

      **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

      - `personAccountParent`
      - `groupParent`
      - `personAccountRdnProperties`
      - `groupRdnProperties`

      The parameters `groupParent` and `personAccountParent` must be set to the same value. For example:

      - `personAccountParent=dc=yourco,dc=com`
      - `groupParent=dc=yourco,dc=com`

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to delete the old attributes before adding the new attributes.

   E. Stop and restart all necessary servers to propagate your changes.

16. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

   A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

   B. Enter a value for `realmName` or leave blank to update the default realm.

   C. Save your changes to the `wkplc.properties` file.

   D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.
E. Stop and restart all necessary servers to propagate your changes.

17. Optional: Run the Member Fixer task to update the member names used by Web Content Management with the corresponding members in the LDAP directory. This step ensures that access to the Web content libraries for the Intranet and Internet Site Templates for the contentAuthors group is correctly mapped to the appropriate group in the LDAP directory.

**Note:** This step is only needed if you have installed the product with Web Content Management and intend to use the Intranet and Internet Site Templates that were optionally installed with the product by running the `configure-express` task.

A. Edit the `wp_profile_root`/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file.

B. Add the following lines to the file:

```
uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN

cn=contentauthors,o=defaultWIMFileBasedRealm -> content_authors_group_DN
```

Replace `portal_admin_DN` with the distinguished name of the portal administrator and `content_authors_group_DN` with the distinguished name of the content authors group used during LDAP configuration.

C. Save your changes and close the file.

D. Run the `./ConfigEngine.sh action-express-memberfixer -DmemberfixerRealm=realm_name -DPortalAdminPwd=password -DWasPassword=password` task, located in the `wp_profile_root`/ConfigEngine directory. **Note:** Choose the appropriate value to enter for `realm_name` depending on the type of LDAP user registry you configured. Table 1. **Value for `realm_name` when running the Member Fixer task to update the member names used by Web Content Management**

<table>
<thead>
<tr>
<th>Type of LDAP</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>standalone ldap realm</code> in the <code>wkplc.properties</code> file.</td>
</tr>
<tr>
<td>Federated LDAP</td>
<td>The value specified for <code>realm_name</code> should match the value for <code>federated realm</code> in the <code>wkplc.properties</code> file. If the value for <code>federated realm</code> is empty, use <code>defaultWIMFileBasedRealm</code> as the default value.</td>
</tr>
</tbody>
</table>

18. If you have created any additional Web Content Management libraries, run the Web content member fixer task to update the member names used by the libraries.

19. Optional: **This step is required in a production environment.** Before removing the file system repository, perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID and administrative group ID with users and groups that exist in the LDAP user registry:

**Important:**
- Before changing the user ID and password, review Special characters in user ID and passwords located under Planning for WebSphere Portal.
- Ensure the new user ID of the WebSphere Application Server administrator is not identical to the one that you are replacing. Duplicate user IDs cause authentication problems with the administrative console.

**Note:** If you run these tasks after you create your cluster, you must run them on all nodes in the cluster.

A. Run the following task from the `wp_profile_root`/ConfigEngine directory: `./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword` **Important:** You must provide the full distinguished name (DN) for the `newAdminId` parameter.
B. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

C. Run the following task from the `wp_profile_root/ConfigEngine directory`: `./ConfigEngine.sh wp-change-portal-admin-user -DWaspPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid`. **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

**Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-skip.ldap.validation=true` parameter to the task to skip the validation.

D. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

20. Optional: **This step is required in a production environment.** Remove the file system repository if you do not use it.

The federated file system user repository that was the default security setting might not be required after federating the user repository. If the file system repository is no longer needed, removing it can help prevent conflicts created by duplicate user identities existing in multiple repositories. See the following topic, which is organized by operating system, for instructions: *Deleting the repository.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring a federated LDAP user registry on Solaris in a clustered environment

Adding a database user registry on Solaris in a clustered environment

Add a database user registry to the default federated repository to store user account information for authentication and authorization. You can add multiple database user registries to the default federated repository although you can only add one database user registry at a time.

In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

If you have WebSphere Application Server Version 7.0.x installed, you must install APAR PM23090 and APAR PM24181 for WebSphere Portal prior to running this task. Clusters with WebSphere Application Server Version 6.1.x do not require these APARs.

Perform the following steps to add a database user registry to the default federated repository; you must repeat these steps for each additional database user registry that you plan to add:

Tip: Perform these steps on the primary node only.

Note: Use the wp_add_DB.properties helper file, located in the wp_profile_root/ConfigEngine/config/helpers directory, when performing this task to ensure the correct properties are entered. In the instructions below, when the step refers to the wkplc.properties file, you will use your wp_add_DB.properties helper file.

1. Set up a new database, including creating a new user with appropriate database privileges for accessing the database:

   Instructions for setting up databases: Refer to the appropriate documentation for the type of database you want to set up.

   Consulting your database administrator: The task of setting up a new database is typically performed by a database administrator. However, the following steps are provided for your reference in the event you are creating a stand-alone database for testing or demonstration purposes. Consult your database administrator before proceeding with the following steps if you plan to create a database for a production environment.

   Table 1. Steps for creating a new database to use as a database user registry.

| SQL Server | Perform the following steps to create an SQL Server database: Install SQL Server. Set Collation to case-sensitive. Note: Install SQL Server with the appropriate portal database collation so that your tempdb collation setting matches the collation you use for the property extension database. The tempdb collation is inherited from the master database, which you set when you install SQL Server. |

2. Perform the following steps to define the **DbDriver** and **DbLibrary** parameter values:
   A. Navigate to the following directory: `wp_profile_root/ConfigEngine/properties`
   B. Locate and open `wpklc_dctype.properties` with any text editor.
   C. Enter a value for the following parameters under the appropriate database type properties heading:
      - `db_type.DbDriver`
      - `db_type.DbLibrary`
   D. Save your changes.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Federated Database Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.
5. Change the value for the `com.ibm.SOAP.requestTimeout` parameter to 1000.
   A. Navigate to the following directory: `wp_profile_root/properties`
   B. Locate and open `soap.client.props` with any text editor.
   C. Locate the `com.ibm.SOAP.requestTimeout` parameter and change the value to 1000.
   D. Save and close `soap.client.props`.

6. Perform the following steps in a clustered environment:
   A. Run the `./ConfigEngine.sh wp-prep-vmm-db-secured-environment -DWasPassword=password -
      DDbDomain=federated.db -Db_type.DmgrDbLibrary=local path of the database jars on the Deployment
      Manager -DDmgrNodeName=dmgr_node_name` task from the `wp_profile_root/ConfigEngine` directory to create the local
      Deployment Manager WebSphere variable used to access the database jars. **Note:** The `db_type` in `db_type`
      `.DmgrDbLibrary` should be set to the type of database you are using, for example `db2`. The `local full path of the`
      `database jars on the Deployment Manager` should be one of the following options:
      - `DB2 Type 2 driver:db2java.zip`
      - `DB2 Type 4 driver:db2jcc.jar;db2jcc_license_cu.jar`
      - `DB2 for z/OS Type 2 driver:db2java.zip`
      - `DB2 for z/OS Type 4 driver:db2jcc.jar;db2jcc_license_cisuz.jar;db2jcc javax.jar`
      - `Oracle:ojdbc14.jar`
      - `SQL Server JDBC driver provided by Microsoft:sqljdbc.jar`
      - `SQL Server JDBC driver provided by DataDirect:sqlserver.jar;base.jar;util.jar`
   B. Run the following task. Include each node name as a comma separated list in the command:
      **Running the task:** You do not have to run this task more than once. You can run this task from any node in the
      cluster.
      1. Set the property value for `federated.db.DbType` in the `wkplc.properties` file if using a database user registry.
      2. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=password -
         DDbDomain=federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the
         database jars` task from the `wp_profile_root/ConfigEngine` directory on each node to create the variable used to
         access the VMM database jars. **Note:** The `VmmNodeName` is a list of one or more WebSphere Portal nodes names in
         the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to
         the type of database you are using, for example `db2`.
      C. Stop and restart all necessary servers to propagate your changes.
   7. Run the `./ConfigEngine.sh wp-create-db -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine`
      directory, to add a database user registry to the default federated repository. **Note:** Users who are not in an LDAP do
not have awareness and cannot see if other users are online. This can happen if you install WebSphere Portal and then enable a Federated LDAP or Federated database user repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Perform the following steps to update the user registry where new users and groups are stored:

   Note: If you are using multiple LDAP user registries and/or a database user registry, only run this task for the user registry that you want to define as the default user registry where new users and groups are stored.

   Attention: During installation, the default file repository creates a default value in the personAccountRdnProperties and groupRdnProperties parameters. To change the default value, you must run this task twice; once to clear the default value and once to add the new value.

A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

B. Enter a value for the following required parameters in the wkplc.properties file under the VMM supported entity types configuration heading:

   Note: See the properties file for specific information about the required parameters and for advanced parameters.
   - personAccountParent
   - groupParent
   - personAccountRdnProperties
   - groupRdnProperties
   The parameters groupParent and personAccountParent must be set to the same value. For example:
   - personAccountParent=dc=yourco,dc=com
   - groupParent=dc=yourco,dc=com

C. Save your changes to the wkplc.properties file.

D. Run the ./ConfigEngine.sh wp-set-entitytypes -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to delete the old attributes before adding the new attributes.

E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Run the ./ConfigEngine.sh wp-query-repository -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to list the names and types of configured repositories.

    If you created your clustered environment then performed the steps in this task, you must now run the enable-jcr-security task on the secondary node. See Enabling LDAP security after cluster creation for instructions.

Parent topic: Configuring the default federated repository on Solaris in a clustered environment

Related tasks
Starting and stopping servers, deployment managers, and node agents
Enabling LDAP security after cluster creation
Adding realm support on Solaris in a clustered environment

A realm is a group of users from one or more user registries that form a coherent group within IBM® WebSphere® Portal. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When configuring realm support, you can perform these steps for each base entry that exists in your LDAP and/or database user registry to create multiple realm support.

Before configuring realm support, you must add all LDAP user registries and/or database user registries, that you will use to create a single realm or multiple realms, to the federated repository. If you are going to create multiple realms, you must create all required base entries within your LDAP user registries and/or database user registries. All base entry names must be unique within the federated repository. In single server environments, you do not have to start or stop the WebSphere_Portal and server1 servers to complete the following steps. In clustered environments, you must stop all application servers on your system, including WebSphere_Portal, then start the nodeagent and deployment manager servers before you begin any of the following steps.

Perform the following steps to add realm support to your user registry model:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.

2. Required: Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:

   - realmName
   - securityUse
   - delimiter
   - addBaseEntry

   Note: See the properties file for specific information about the required parameters and for advanced parameters.

3. Save your changes to the wkplc.properties file.

4. Run the ./ConfigEngine.sh wp-create-realm -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add a new realm to the Virtual Member Manager configuration. Important: To create multiple realms, ensure that your federated repository contains the required unique base entries. Stop and restart the appropriate servers for your installation environment, and then update the wkplc.properties file with the base entry information and rerun the wp-create-realm task. Repeat these steps until all realms are created.

5. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

6. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading and then save your changes:

   - realmName
   - realm.personAccountParent
   - realm.groupParent
   - realm.orgContainerParent

   Note: See the properties file for specific information about the required parameters and for advanced parameters.

7. Run the ./ConfigEngine.sh wp-modify-realm-defaultparents -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to update the default parents per entity type and realm. Important: Stop and restart the appropriate servers for your installation environment before rerunning this task for any additional entity types.
and realms.

8. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

9. Optional: Perform the following steps to add additional base entries to the realm configuration; for example, if you had two additional base entries (base entry 1 and base entry 2) to add to the realm you just created, you would update the wkplc.properties file with the information from base entry 1 and then run this task. Then you would update the properties file with the information for base entry 2 and then run this task:
   A. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
   B. Enter a value for the following required parameters in the wkplc.properties file under the VMM realm configuration heading:
      - realmName
      - addBaseEntry
   C. Save your changes to the wkplc.properties file.
   D. Run the ./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, to add additional LDAP base entries to the realm configuration.
   E. Stop and restart all necessary servers to propagate your changes.

10. Optional: Perform the following steps to replace the WebSphere Application Server and WebSphere Portal administrator user ID; this step is required if you change the default realm:
    A. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Application Server administrative user.
    B. Create a new user in the Manage Users and Groups portlet to replace the current WebSphere Portal administrative user.
    C. Create a new group in the Manage Users and Groups portlet to replace the current group.
    D. Run the ./ConfigEngine.sh wp-change-was-admin-user -DWasPassword=password -DnewAdminId=newadminId -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupId task, from the wp_profile_root/ConfigEngine directory, to replace the old WebSphere Application Server administrative user ID and group ID with the new user and group.Important: You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.
    E. Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.
    F. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.
    G. Run the ./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminId -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupId task to replace the old WebSphere Portal administrative user ID and group ID with the new user and group.Important: You must provide the full distinguished name (DN) for the newAdminId and newAdminGroupId parameters.
    H. Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the -Dskip.ldap.validation=true parameter to the task to skip the validation.
    I. Verify that the task completed successfully. In a clustered environment, restart the deployment manager, the node agent(s), and WebSphere_Portal servers. In a standalone environment, restart the server1 and WebSphere_Portal servers.

11. Optional: Perform the following steps to set the realm you created as the default realm:Remember: Only users defined in base entries that exist in the default realm are able to log into WebSphere Portal. If you find that a user cannot log in to WebSphere Portal, check to see if the base entry that contains the user exists in the default realm. You can run the wp-query-realm-baseentry task to see what base entries are part of the default realm. If the default realm is missing
the base entry, run the `wp-add-realm-baseentry` task to add the base entry to the default realm.

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. For `defaultRealmName`, type the `realmName` property value you want to use as the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-default-realm -DWasPassword=password` task, from the `wp_profile_root` directory, to set this realm as the default realm.

E. Stop and restart all necessary servers to propagate your changes.

12. Optional: Perform the following steps to query a realm for a list of its base entries:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. For `realmName`, type the name of the realm you want to query.

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-query-realm-baseentry -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, to list the base entries for a specific realm.

13. Optional: Perform the following steps to enable the full distinguished name login if the short names are not unique for the realm:

A. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

B. Enter a value for `realmName` or leave blank to update the default realm.

C. Save your changes to the `wkplc.properties` file.

D. Run the `./ConfigEngine.sh wp-modify-realm-enable-dn-login -DWasPassword=password` task, located in the `wp_profile_root/ConfigEngine` directory, to enable the distinguished name login. **Note:** After running this task to enable the full distinguished name login, you can run the `./ConfigEngine.sh wp-modify-realm-disable-dn-login -DWasPassword=password` task to disable the feature.

E. Stop and restart all necessary servers to propagate your changes.

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Parent topic:** Configuring the default federated repository on Solaris in a clustered environment

**Related tasks**

Adapting the attribute configuration

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you will need to adapt the attribute configuration to match the configured LDAP server(s) and your business needs. However, you do not need to perform these steps if you are using either a database user registry or the default federated file-based repository for out-of-box installations.

After installation, IBM WebSphere Portal has a predefined set of attributes for users and groups. Your LDAP server may have a different set of predefined user and group attributes. To ensure proper communication between WebSphere Portal and your LDAP server, you can configure additional attributes and flag existing attributes as required or unsupported on a per repository basis or for all configure repositories.

LDAP servers can only handle attributes that are explicitly defined in their schema. The LDAP server’s schema is different from the WebSphere Portal schema but the two schemas should match for proper communication between WebSphere Portal and the LDAP server. The task to add the LDAP user registry does some basic attribute configurations depending on the type of LDAP server that you choose. You may, however, still need to adapt the WebSphere Portal configuration to match the LDAP schema; for example, if an attribute is defined in WebSphere Portal but not in the LDAP server, you will need to perform one of the following tasks to resolve this mismatch:

- Flag the attribute as unsupported for the LDAP server
- Introduce an attribute mapping that maps the WebSphere Portal attribute to an attribute defined in the LDAP schema

Perform the following tasks to adapt the attribute configuration to match the configured LDAP server(s) and your business needs:

1. **Querying the defined attributes on Solaris**
   After installing IBM WebSphere Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

2. **Adding attributes on Solaris in a clustered environment**
   The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM WebSphere Portal and your user registry.

3. **Mapping attributes on Solaris in a clustered environment**
   After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

4. **Removing attributes**
   Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

**Parent topic:** Choosing your user registry model on Solaris in a clustered environment

**Related tasks**
- Adding an LDAP user registry on Solaris
- Adding an LDAP user registry over SSL on Solaris
- Configuring a stand-alone LDAP user registry on Solaris
Configuring a stand-alone LDAP user registry over SSL on Solaris
Querying the defined attributes on Solaris

After installing IBM® WebSphere® Portal and configuring your LDAP user registries, you can query the defined attributes to see what attributes are flagged as unsupported or if the attribute is mapped to a different LDAP attribute.

**Warning:** If you are using a database user registry or a property extension database, copy the database drivers to the `AppServer_root/lib` directory before executing this script.

Run the `./ConfigEngine.sh wp-query-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory, any time during the configuration process or at runtime to query an overview of the currently defined attributes. This task creates the `availableAttributes.html` report, located in the `wp_profile_root/ConfigEngine/log` directory. The report contains one table that lists the available attributes for Users (PersonAccount) and one table that lists the available attributes for Groups. For each configured repository there is a column that indicates if the attribute is flagged as unsupported or if the attribute is mapped to a different LDAP attribute. **Note:** This task does not validate the existence of attributes in the LDAP schema.

**Parent topic:** Adapting the attribute configuration

**Next topic:** Adding attributes on Solaris in a clustered environment
Adding attributes on Solaris in a clustered environment

The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. If this is the case, extend the VMM attribute schema by adding new attributes that you can map between IBM® WebSphere® Portal and your user registry.

Perform the following steps to add new attributes to your user registry:

1. Install the required Enterprise Archive (.ear) file on WebSphere Application Server. Select the appropriate task to install the .ear file:

   **Table 1. Steps for installing the .ear file by environment**

<table>
<thead>
<tr>
<th>Environment</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Stand-alone environment</strong></td>
<td>Perform the following steps to install the .ear file in a stand-alone environment: Open a command prompt. Navigate to the <code>wp_profile_root/ConfigEngine</code> directory. Run the <code>./ConfigEngine.sh wp-la-install-ear -DWasPassword=password</code> task.</td>
</tr>
<tr>
<td><strong>Clustered environment</strong></td>
<td>Perform the following steps to install the .ear file in a clustered environment: Open a command prompt. Navigate to the <code>wp_profile_root/ConfigEngine</code> directory on the primary node. Run the <code>./ConfigEngine.sh wp-la-install-ear -DWasPassword=dmgr_password -DServerName=dmgr -DNodeName=node_name</code> task. Where <code>node_name</code> is the name of the node where the deployment manager resides; you can find the <code>node_name</code> value in the WebSphere Application Server Administrative Console under System administrator &gt; Deployment Manager &gt; Runtime tab &gt; General Properties &gt; Node Name.</td>
</tr>
</tbody>
</table>

2. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: Starting and stopping servers, deployment managers, and node agents.

3. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.

4. Enter a value for the following required parameters in the `wkplc.properties` file under the VMM Property Extension Properties heading: Note: See the properties file for specific information about the required parameters and for advanced parameters.

   - `la.providerURL`
   - `la.propertyName`
   - `la.entityTypes`
   - `la.dataType`
   - `la.multiValued`

5. Save your changes to the `wkplc.properties` file.
6. Run the `./ConfigEngine.sh wp-add-property -DWasPassword=password` task to add the attribute to the user registry.

   **Note:** This task performs an EJB call to WebSphere Application Server, which must authenticate against WebSphere Application Server. Depending on the configuration in the `sas.client.props` file, you may receive a popup window or a command line prompt asking for user identity and password. Enter the WebSphere Application Server user ID and password.

   **Remember:** If you have multiple properties to add, repeat all steps, except for the `wp-la-install-ear` task, until all new attributes are added.

7. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents.*

If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.

**Previous topic:** Querying the defined attributes on Solaris

**Next topic:** Mapping attributes on Solaris in a clustered environment

### Related tasks
- Starting and stopping servers, deployment managers, and node agents
- Enabling LDAP security after cluster creation
Mapping attributes on Solaris in a clustered environment

After you install and configure your LDAP user registry and after you query the defined attributes, you can map the attributes so they match the configured LDAP servers and your business needs.

Perform the following steps to map attributes between WebSphere Portal and your LDAP server; if you have multiple LDAP servers, you will need to perform these steps for each LDAP server:

1. Use a text editor to open the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory.
2. Enter a value for one of the following sets of parameters in the wkplc.properties file to identify your LDAP server:
   - **Note:** Make sure you use the same values you used to configure your LDAP server.
   - **Table 1. Identifying your LDAP server in the wkplc.properties file.**

3. Run one of the following tasks to check that all defined attributes are available in the configured LDAP user registry:
   - **Table 2. Task to check that all defined attributes are available in the configured LDAP user registry.**

4. Open the ConfigTrace.log file, located in the wp_profile_root/ConfigEngine/log directory, to review the following output for the PersonAccount and Group entity type:
- The following attributes are defined in WebSphere Portal but not in the LDAP server
  - This list contains all attributes that are defined in WebSphere Portal but not available in the LDAP. Flag attributes that you do not plan to use in WebSphere Portal as unsupported. Map the attributes that you plan to use to the attributes that exist in the LDAP; you must also map the `uid`, `cn`, `firstName`, `sn`, `preferredLanguage`, and `ibm-primaryEmail` attributes if they are contained in the list.

- The following attributes are flagged as required in the LDAP server but not in WebSphere Portal
  - This list contains all attributes that are defined as "MUST" in the LDAP server but not as required in WebSphere Portal. You should flag these attributes as required within WebSphere Portal; see the step below about flagging an attribute as either unsupported or required.

- The following attributes have a different type in WebSphere Portal and in the LDAP server
  - This list contains all attributes that WebSphere Portal might ignore because the data type within WebSphere Portal and within the LDAP server do not match.

5. Use a text editor to open the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine/properties` directory.
6. Enter a value for one of the following sets of parameters in the `wkplc.properties` file to correct any issues found in the config trace file: `Table 3. Parameters to define in the wkplc.properties file to correct any issues found in the config trace file`.

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td>The following parameters are found under the LDAP attribute configuration heading: <strong>Note</strong>: See the properties file for specific information about the required parameters and for advanced parameters.</td>
</tr>
</tbody>
</table>

|                 | `standalone.id`standalone.ldap.attributes.mapping.entityTypes=
|                 | `PersonAccount, Group` |
7. Save your changes to the `wkplc.properties` file.

8. Run one of the following tasks to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between WebSphere Portal and the LDAP user registry:

   **Table 4. Task to update the LDAP user registry configuration with the list of unsupported attributes and the proper mapping between Portal and the LDAP user registry.**

<table>
<thead>
<tr>
<th>Repository type</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stand-alone</td>
<td><code>./ConfigEngine.sh wp-update-standalone-ldap-attribute-config -DWasPassword=password</code> task, from the <code>wp_profile_root/ConfigEngine</code> directory</td>
</tr>
<tr>
<td>Federated</td>
<td><code>./ConfigEngine.sh wp-update-federated-ldap-attribute-config -DWasPassword=password</code> task, from the <code>wp_profile_root/ConfigEngine</code> directory</td>
</tr>
</tbody>
</table>

9. Stop and restart the appropriate servers to propagate the changes. For specific instructions, see the following link under Related tasks: *Starting and stopping servers, deployment managers, and node agents.*

10. Optional: Perform the following steps to flag an attribute as either unsupported or required for the entire WebSphere Portal environment instead of just for the specified LDAP:

    A. Enter a value for the following required parameters in the `wkplc.properties` file: **Note:** See the properties file for specific information about the required parameters and for advanced parameters.

        - `user.attributes.required`
        - `user.attributes.nonsupported`

    B. Save your changes to the `wkplc.properties` file.

    C. Run the `./ConfigEngine.sh wp-update-attribute-config -DWasPassword=password` task, from the `wp_profile_root/ConfigEngine` directory.

    D. Stop and restart all necessary servers to propagate your changes.

    If you created your clustered environment then performed the steps in this task, you must now run the `enable-jcr-security` task on the secondary node. See *Enabling LDAP security after cluster creation* for instructions.
Removing attributes

Due to a Virtual Member Manager (VMM) limitation, there is currently no task to update an attribute. Therefore, if you added an attribute to your property extension database or when adapting attributes to match your LDAP server that were spelled incorrectly or already added due to migration, you must remove the attribute from the database. Use caution when performing these steps.

Perform the following steps to remove an attribute from your database:

**Important:** Do not remove attributes that have already been populated with user values because this can cause database inconsistencies.

**Cluster note:** In a clustered environment, perform the following steps on the deployment manager and then resynch the nodes.

1. Perform the following steps to remove an attribute stored in a property extension database; this is an attribute that was added using the `wp-add-la-property` task.
   - A. Open the tool you use to edit your database.
   - B. Verify that your attribute name is available in the LAPROP table.
   - C. Delete the required attributes from the LAPROP table.
   - D. Open the `wimxmlextension.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/model` directory.
   - E. Locate and delete the `propertySchema` definition for the attributes that you deleted from the LAPROP table; for example:
     ```xml
     <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
     </wim:propertySchema>
     ```
   - F. Save your changes to the `wimxmlextension.xml` file.
   - G. Open the `wimconfig.xml` file, located in the `wp_profile_root/config/cells/cellname/wim/config` directory.
   - H. Locate and delete the `propertiesNotSupported` definitions for the attributes that you deleted from the LAPROP table; for example:
     ```xml
     <config:propertiesNotSupported name="attribute_name"/>
     ```
   - I. Save your changes to the `wimconfig.xml` file.
   - J. Stop and restart the server1 and WebSphere_Portal servers from the `wp_profile_root/bin` directory.

2. Perform the following steps to remove an attribute that is not stored in a property extension database:
   - A. Open the `wimxmlextension.xml` file.
   - B. Locate and delete the `propertySchema` definition for the attributes you previously added; for example:
     ```xml
     <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String" multiValued="true" propertyName="attribute_name">
     <wim:applicableEntityTypeNames>PersonAccount</wim:applicableEntityTypeNames>
     </wim:propertySchema>
     ```
   - C. Save your changes to the `wimxmlextension.xml` file.
   - D. Open the `wimconfig.xml` file.
   - E. Locate and delete the stanza that corresponds to the custom attribute you deleted from the `wimextension.xml` file; for example:
     ```xml
     <config:attributes name="attribute_name" propertyName="property_name">
     <config:entityTypes>PersonAccount</config:entityTypes>
     </config:attributes>
     ```
   - F. Save your changes to the `wimconfig.xml` file.
G. Stop and restart the server1 and WebSphere_Portal servers.

**Parent topic:** Adapting the attribute configuration  
**Previous topic:** Mapping attributes on Solaris in a clustered environment
Preparing additional nodes on Solaris

After installing and configuring your primary node, you can create your secondary nodes. You must install IBM® WebSphere® Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris
  - Installing a secondary node after migrating from previous version

Perform the following tasks to prepare your secondary node:

- **Installing WebSphere Portal on Solaris on the additional nodes**
  Install IBM WebSphere Portal on your secondary nodes to create a highly available and scalable environment.

- **Choosing the type of additional node to create on Solaris**
  If you created a static cluster using the IBM WebSphere Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

- **Choosing the type of vertical cluster to create on Solaris**
  If you are using the IBM WebSphere Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

**Parent topic:** Setting up a cluster on Solaris

**Previous topic:** Configuring WebSphere Portal to use a user registry on Solaris in a clustered environment

**Next topic:** Tune your servers
Installing WebSphere Portal on Solaris on the additional nodes

Install IBM® WebSphere® Portal on your secondary nodes to create a highly available and scalable environment. Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method. **Note:** If you plan to use IBM WebSphere Application Server Version 7.0, you must purchase and install it before installing WebSphere Portal on the existing WebSphere Application Server Version 7.0 instance.

Perform the following steps to install WebSphere Portal:

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   
   **Restriction:** Installing WebSphere Portal Version 6.1.0.1 or higher on an existing WebSphere Application Server Version 7.0 instance where WebSphere Portal Version 7.0 was installed is unsupported.

   **Important:** Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities

3. Optional: Perform the following steps if you want to install WebSphere Portal using a non-root user:

   **Restriction:** Although it is possible to install WebSphere Application Server as a non-root user, there are limitations to this option that can affect WebSphere Portal functionality, which is why you should install WebSphere Application Server as a root user.

   **A.** Install the current supported version of WebSphere Application Server as a root user.

   **B.** Open a command prompt and perform the following steps to create a non-root user and to change ownership:

   1. Use the appropriate system commands to create a new group, to create a new user, and to add the new user to the new group.
      
      `chgrp -R group_name/opt/IBM`
      
      `chmod -R g+rw /opt/IBM`
      
      `chgrp -R group_name /tmp`
      
      `chmod -R g+wr /tmp`
      
      `chgrp -R group_name /var/tmp`
      
      `chmod -R g+wr /var/tmp`
chgrp -R group_name /var/tmp

C. Launch the installation program per the next step. During the installation, select the existing WebSphere Application Server using the non-root user and set the installation location to a unique location under the path where non-root permissions were granted.

4. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information: Advance installation parameters: To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.

**Restriction:** When defining your installation path, the **ONLY** supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Graphical user interface</td>
<td>./install.sh</td>
</tr>
<tr>
<td>Console mode</td>
<td>./install.sh -console from the PortalExpress subdirectory</td>
</tr>
<tr>
<td>Silent Install</td>
<td>./install.sh -options &quot;path_to_file/response_filename&quot;, where path_to_file is the full path to the response file and response_filename is the name of the file. A sample install response file (installresponse.txt) and a sample uninstall response file (uninstallresponse.txt) are located in the setup CD root directory. <strong>Important:</strong> Do not place the response file in a path that contains a space and do not put a space in the file name.</td>
</tr>
</tbody>
</table>

**Important:** If you have a Solaris 9 on Sun SPARC, you MUST either add the `-W defaults.force32bit=true` parameter to your installation command or install the 32-bit WebSphere Application Server product before installing WebSphere Portal to prevent the installer from automatically selecting a 64-bit environment.

5. Verify your installation was successful; access WebSphere Portal using the `http://yourserver:yourport/wps/portal` format. Run the `./ConfigEngine.sh list-server-ports -DWasPassword=password` task from the `wp_profile_root/ConfigEngine/log/wp_PortMatrix.txt` file that lists WebSphere Portal ports for your installation.

6. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

**Note:** The starting port parameter is required for a successful completion of the `modify-ports-by-startport` task. Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the `modify-ports-by-startport` task.

A. Stop the server1 and WebSphere Portal servers.
B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>./ConfigEngine.sh modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>
C. Restart the server1 and WebSphere_Portal servers.

7. To prevent Out of Memory errors, perform the following steps to set the MaxPermSize:

   Tip: If Maximum Heap Size is set to 2048 M or higher, set the MaxPermSize to a quarter of the value entered for the Maximum Heap Size; for example, if your Maximum Heap Size is 3000 M, set MaxPermSize to 750 M. If your Maximum Heap Size is less than 2048 M, set MaxPermSize to 512 M.

   A. Log in to the WebSphere Application Server Administration Console.
   B. Click Servers > Server Types > WebSphere application servers > WebSphere_Portal.
   D. In the Generic JVM arguments field, change the MaxPermSize value to -XX:MaxPermSize=numeric value, where numeric value is a quarter of the value entered for the Maximum Heap Size. Important: If MaxPermSize does not exist in the Generic JVM arguments field, add it to the field but do not replace existing information in the Generic JVM arguments field with the MaxPermSize information.
   E. Click OK to save your changes.
   F. Click Save to save your changes to the master configuration.
   G. Log out of the WebSphere Application Server Administration Console.
   H. Restart the server1 and WebSphere_Portal servers.

8. Perform the following steps if you migrated from a previous version of WebSphere Portal:

   A. Log on to the WebSphere Application Server Administrative Console.
   C. Click WP Identification.
   D. Click Custom properties.
   E. If applicable, note the location of the LpidToGupidMapping.properties file.
   F. If the LpidToGupidMapping.properties file exists on the primary node, copy the file to the same location on the secondary node.

Choosing the type of additional node to create on Solaris

If you created a static cluster using the IBM® WebSphere® Application Server Network Deployment, add additional static nodes to the cluster. If you created a dynamic cluster using IBM WebSphere Virtual Enterprise, add additional dynamic nodes to the cluster.

Choose one of the following options to add additional nodes to your cluster:

- **Adding additional nodes to the static cluster on Solaris**
  After installing IBM WebSphere Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

- **Adding an additional node to an existing dynamic cluster**
  After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM WebSphere Virtual Enterprise dynamic cluster.

**Parent topic:** Preparing additional nodes on Solaris
Adding additional nodes to the static cluster on Solaris

After installing IBM® WebSphere® Portal on your secondary node, you must add the node to the cluster to create a highly available environment.

Perform the following steps to add the secondary node to the cluster:

1. Perform the following steps on the secondary node to access your database server:
   Note: All properties files are located in the `wp_profile_root`/ConfigEngine/properties directory.
   A. For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   B. For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   C. Set all database properties in the `wkplc_dbtype.properties` and `wkplc_comp.properties` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   A. `./ConfigEngine.sh validate-database-driver` -
      `DTransferDomainList=release,customization,community,jcr,feedback,likeminds` `-DWasPassword=password`
   B. `./ConfigEngine.sh validate-database-connection` `-DWasPassword=password` -
      `DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root`/ConfigEngine/properties directory of the secondary node:
   Note: Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   A. Verify that `WasUserid` is set to your deployment manager administrator ID.
   B. Verify that `WasPassword` is set to your deployment manager administrator password.
   C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is 8879.
   G. Verify that `PrimaryNode` is set to `false`.
   H. Verify that `ClusterName` is set to the primary node’s `ClusterName`.

4. Run the `./ConfigEngine.sh cluster-node-config-pre-federation` `-DWasPassword=dmgr_password` task, from the `wp_profile_root`/ConfigEngine directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
   Note: You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.
   A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.
   **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user
registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

6. Run the `./ConfigEngine.sh wp-node-prep-vmm-db-secured-environment` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the `ServerName` parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for `newAdminGroupId` contains a space; for example Software Group, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Optional: Open the `wkplc.properties` file and change the `ServerName` parameter from the default `WebSphere_Portal_nodename` value to a value that meets your business needs. Do not change the parameter to `WebSphere_Portal` as this is the primary node value.

9. Run the `./ConfigEngine.sh cluster-node-config-cluster-setup` task to add the node to your cluster.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select **Environment > WebSphere Variables.**
   C. From the **Scope** drop-down menu, select the `Node=nodename`, `Server=servername` option to narrow the scope of the listed variables, where `Node=nodename` is the node that contains the application server.
D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

12. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Choosing the type of additional node to create on Solaris

**Related tasks**

Deleting passwords from properties files
Adding an additional node to an existing dynamic cluster

After creating your dynamic cluster, you can add additional nodes to expand the capacity of the dynamic cluster. Install and configure the additional node, then add it to the existing dynamic cluster node group, and then add it to the existing IBM® WebSphere® Virtual Enterprise dynamic cluster.

On all WebSphere Portal nodes, install WebSphere Virtual Enterprise and augment the wp_profile profile. See Installing and configuring the product for information about installing WebSphere Virtual Enterprise. See Augmenting profiles for information about augmenting the Deployment Manager and wp_profile profiles.

- Prerequisites
  - PK97393 for all WebSphere Application Server Versions prior to 6.1.0.5
  - Installing and configuring the product:
    - Augmenting profiles

Perform the following steps to add an additional node to an existing WebSphere Virtual Enterprise dynamic cluster:

1. Perform the following steps on the secondary node to access your database server:
   - Note: All properties files are located in the `wp_profile_root/ConfigEngine/properties` directory.
   - For JDBC Type 2 connections only, ensure that the database client software is installed on the secondary node using the same settings as the primary node and that you can connect to the remote database. It is not necessary to create databases or users when configuring secondary nodes. **DB2 users:** When using DB2, you must catalog the TCP/IP node and all databases used on each secondary node. For more information refer to Preparing DB2.
   - For JDBC Type 4 connections only, copy the JDBC Type 4 jar files to the secondary node from the DB2 server.
   - Set all database properties in the `wkplc_dbtype.properties` and `wkplc_comp.properties` files with the appropriate values from the primary node.

2. Run the following tasks to validate your database settings:
   - A. `./ConfigEngine.sh validate-database-driver`
     - `DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password`
   - B. `./ConfigEngine.sh validate-database-connection`
     - `DWasPassword=password`
     - `DTransferDomainList=release,customization,community,jcr,feedback,likeminds`

3. Stop the server1 and WebSphere_Portal servers on the secondary node and ensure that the following parameters are set correctly in the `wkplc.properties` file, located in the `wp_profile_root/ConfigEngine\properties` directory of the secondary node:
   - Note: Although you can add these parameters directly to any task that you run while creating your cluster, you may want to add them to the properties file while creating your cluster and then remove them when you are finished to keep your environment secure.
   - A. Verify that `WasUserId` is set to your deployment manager administrator ID.
   - B. Verify that `WasPassword` is set to your deployment manager administrator password.
   - C. Verify that `PortalAdminId` is set to your WebSphere Portal administrator ID.
   - D. Verify that `PortalAdminPwd` is set to your WebSphere Portal password.
   - E. Verify that `WasRemoteHostName` is set to the fully qualified host name of the deployment manager.
   - F. Verify that `WasSoapPort` is set to the SOAP port that the deployment manager is using; the default value is 8879.
   - G. Verify that `PrimaryNode` is set to `false`. 
H. Verify that ClusterName is set to the primary node's ClusterName.

4. Run the `/ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=dmgr_password` task, from the `wp_profile_root/ConfigEngine` directory of the secondary node.

5. Optional: If you configured a database user registry or a property extension (lookaside) database, run the following task to set up access to the database drivers:
   
   **Note:** You will also need to run this task if you migrated the primary node from a release prior to Version 6.1.0, even if you did not configure a database user registry or a property extension (lookaside) database.
   
   A. Set the property value for `federated.db.DbType` if using a database user registry or set the property value for `la.DbType` if using a property extension database in the `wkplc.properties` file.
   
   **Note:** If you migrated the primary node from a version prior to Version 6.1.0 and you are not using a database user registry or a property extension database, set the property value for `federated.db.DbType` to the same value that is in the `wkplc.properties` file on the primary node.

   B. Run the `/ConfigEngine.sh wp-node-prep-vmm-db-secured-environment -DWasPassword=dmgr_password -DDbDomain=la|federated.db -DVmmNodeName=node_name -Db_type.NodeDbLibrary=local full path of the database jars` task from the `wp_profile_root/ConfigEngine` directory to create the variable used to access the VMM database jars.
   
   **Note:** `VmmNodeName` is a list of one or more WebSphere Portal nodes names in the cell which share the same database driver paths. The `db_type` in `db_type.NodeDbLibrary` should be set to the type of database you are using, for example `db2`.

6. Run the `/ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task. **Note:** If you want to customize the WebSphere Portal server name (WebSphere_Portal) for your additional node, set the `ServerName` parameter in the `wkplc.properties` file after running the `cluster-node-config-post-federation` task.

7. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell's user registry. Run the `/ConfigEngine.sh wp-change-portal-admin-user -DWasPassword= -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

   **Attention:** The password value for `-DWasPassword` is the Deployment Manager administrative password.

   **Important:** You must provide the full distinguished name (DN) for the `newAdminId` and `newAdminGroupId` parameters.

   **Additional parameter for stopped servers:** This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

   **Fast path:** If the value for `newAdminGroupId` contains a space; for example `Software Group`, open the `wkplc.properties` file and add the values for `newAdminId`, `newAdminPw`, and `newAdminGroupId`. Save your changes and run the `ConfigEngine.bat wp-change-portal-admin-user -DWasPassword=dmgr_password` task.

   **Important:** If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere_Portal server to use the updated administrator user ID.

   **Note:** The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the `wkplc.properties` file if required.

8. Log on to the deployment manager administrative console.

9. Perform the following steps to add members to the node group:
   
   A. Click **System administration > Node groups.**
B. Click on the name of the node group that you want to add members to.
C. Click Node group members under Additional Properties.
D. Click Add.
E. Select the additional node you want to add into the node group and then click Add.
F. Click the Save link to save your changes to the master configuration.

10. Wait at least 30 minutes before stopping and restarting the deployment manager because the node agent runs a background thread to expand all EAR files into their target directories. **Note:** Attempting to restart the deployment manager while the expansion is in process can result in an unusable application. Although the time to complete an EAR expansion is environment-dependent, a 30 minute wait is sufficient for a typical environment.

11. Define or verify the following parameters in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:

   A. Set ClusterName to the name of the existing dynamic cluster.
   B. Verify that CellName is set to the deployment manager cell.
   C. Verify that NodeName is set to the local WebSphere Portal node.
   D. Set ServerName to the server that will be used for the dynamic cluster member on this node. **Note:** Log on to the deployment manager administrative console and click Dynamic Clusters > PortalCluster > Dynamic cluster members to find the name of the server used for the dynamic cluster.
   E. Verify that PrimaryNode is set to false because this is an additional node.

12. Run the `./ConfigEngine.sh cluster-node-config-dynamic-cluster-setup -DWasPassword=dmgr_password` task to add the new member to the existing dynamic cluster. **Note:** This task may display a warning message since the cluster already exists but it will proceed to create the new dynamic cluster; therefore, the warning can be ignored.

13. Perform the following steps to start the cluster member:

   A. Log on to the Deployment Manager administrative console.
   B. Navigate to Servers > Dynamic clusters > cluster name > Dynamic cluster members.
   C. Select the cluster member and click Start.
   D. Log off of the deployment manager administrative console.

14. Perform the following steps to access the Web Content Management content through an external Web server:

   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Resynchronize.
   G. Log off of the deployment manager administrative console.

15. Run the following tasks to propagate your changes. **Note:** WebSphere_Portal_nodename is the name of the node’s WebSphere Portal server; but if you customized the server name, the default name changes. If you are uncertain of the server name, run the `serverstatus -all` task to get a list of the server names and their status.

   A. `./stopManager.sh -username admin_userid -password admin_password`, from the dmgr_profile_root/bin directory
   B. `./stopNode.sh -username admin_userid -password admin_password`, from the wp_profile_root/bin directory
   C. `./stopServer.sh WebSphere_Portal_nodename -username admin_userid -password admin_password`
D. ./startManager.sh, from the dmgr_profile_root/bin directory
E. ./startNode.sh, from the wp_profile_root/bin directory
F. ./startServer.sh WebSphere_Portal_nodename

16. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See "Deleting passwords from properties files" under Related tasks for information.

**Parent topic:** Choosing the type of additional node to create on Solaris

**Related tasks**
Deleting passwords from properties files
Choosing the type of vertical cluster to create on Solaris

If you are using the IBM® WebSphere® Application Server Network Deployment, you can add vertical cluster members to your static cluster. If you are using IBM WebSphere Virtual Enterprise, you can add vertical cluster members to your dynamic cluster.

Choose one of the following options to add vertical cluster members to your cluster.

- Adding vertical cluster members to a static cluster on Solaris
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

- Adding vertical cluster members to a dynamic cluster on Solaris
  You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

*Parent topic:* Preparing additional nodes on Solaris
Adding vertical cluster members to a static cluster on Solaris

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Log into the deployment manager administrative console.
2. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:
   - For **WebSphere Application Server Version 6.1**: Click **Servers > Clusters** in the console navigation tree, select the cluster name, and then click **Cluster members** from the list of additional properties.
   - For **WebSphere Application Server Version 7.0**: Click **Servers > Clusters > WebSphere application server clusters > cluster_name > Cluster members**.
3. Click **New** to create the cluster member.
   - A. Define the name of cluster member. **Note:** Do not use spaces in the cluster member name.
   - B. Select an existing node where IBM® WebSphere® Portal is installed.
   - C. Check the box **Generate Unique HTTP Ports**.
   - D. Click **Add Member** and then click **Next** to view the summary.
     **Important:** You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an "*" wildcard character for the host name). See Configuring virtual hosts for information.
4. Click **Finish**, and save the changes.
   - The new cluster topology can be viewed from the **Servers > Cluster Topology** view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the **Servers > Clusters > Cluster Topology** view.
   - The **Servers > Application Servers** view will list the new server cluster members. If using WebSphere Application Server Version 7.0, the **Servers > Server Types > WebSphere application servers** view will list the new server cluster members.
5. Perform the following steps to enable cache replication:
   - A. From the deployment manager Administrative Console, navigate to **Servers > Application servers** and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to **Servers > Server Types > WebSphere application servers** and then click the new vertical cluster member(s).
   - B. Click **Dynamic cache service** under **Container services**.
   - C. Change **Cache size** to 3000 entries.
   - D. Check the **Enable cache replication** check box.
   - E. Select **NOT_SHARED** from the **Replication type** drop-down menu.
   - F. Click **OK**.
   - G. Click **Save** to save your changes to the master configuration.
6. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   - A. Run the `./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password` task, from the **wp_profile_root/ConfigEngine** directory, where **unique vertical cluster servername** is the name you specified when you created the cluster member.
   - B. Restart the vertical cluster member referenced in the `cluster-node-config-vertical-cluster-setup` task.
7. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
   B. Select Environment > WebSphere Variables.
   C. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server.
   D. Update the WCM_HOST variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.
   E. Update the WCM_PORT variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.
   F. Perform the following steps to synchronize the node with the deployment manager:
      1. Select System Administration > Nodes.
      2. Select the node that you want to synchronize from the list.
      3. Click Full Resynchronize.
   G. Log off of the deployment manager administrative console.

8. Save your changes and resynchronize the nodes.
   A. In the administrative console for the deployment manager, click Save on the task bar, and save your administrative configuration.
   B. Select System Administration > Nodes, select the node from the list, and click Full Resynchronize.

9. Regenerate the Web server plug-in.
   A. Regenerate the Web server plug-in using the deployment manager administrative console.
   B. If you are using a remote Web server, copy the updated plug-in configuration file (plugin-cfg.xml) to the Web server’s plug-in configuration directory.

10. Stop and start the Web server.

Parent topic: Choosing the type of vertical cluster to create on Solaris
Adding vertical cluster members to a dynamic cluster on Solaris

You can add vertical cluster members to share the workload demands of your cluster across multiple members running on the same physical machine.

Perform the following steps to add a vertical cluster member to your clustered environment:

1. Open a browser and enter http://DM01:9060/ibm/console in the address bar to access the administrative console on the deployment manager, where DM01 is the deployment manager node or host name. The port number might differ based on your installation.

2. Perform the following steps to allow vertical clusters on your dynamic cluster:
   A. Navigate to Servers > Dynamic clusters and select the appropriate dynamic cluster.
   B. Select the Allow more than one instance to start on the same node check box under Vertical stacking of Instances on node.
   C. Enter a new value in the Number of instances text box to determine the number of vertical cluster members allowed on each node.
   D. Click Apply and then click Save to save the changes to the master configuration.

   - The new cluster topology can be viewed from the Servers > Cluster Topology view. If using WebSphere Application Server Version 7.0, the new cluster topology can be viewed from the Servers > Clusters > Cluster Topology view.
   - The Servers > Application Servers view will list the new server cluster members. If using WebSphere Application Server Version 7.0, the Servers > Server Types > WebSphere application servers view will list the new server cluster members.

   **Important:** You must update the virtual host entries for the new port created when adding a cluster member. You can do this by updating the default_host virtual host in the administrative console and adding a new alias entry for the port number (use an “*” wildcard character for the host name). See Configuring virtual hosts for information.

3. Perform the following steps to enable cache replication:
   A. From the deployment manager Administrative Console, navigate to Servers > Application servers and then click the new vertical cluster member(s). If using WebSphere Application Server Version 7.0, navigate to Servers > Server Types > WebSphere application servers and then click the new vertical cluster member(s).
   B. Click Dynamic cache service under Container services.
   C. Change Cache size to 3000 entries.
   D. Check the Enable cache replication check box.
   E. Select NOT_SHARED from the Replication type drop-down menu.
   F. Click OK.
   G. Click Save to save your changes to the master configuration.

4. Perform the following steps on each vertical cluster member to clean up the server-scoped resources, caches, and resource providers:
   A. Run the ./ConfigEngine.sh cluster-node-config-vertical-cluster-setup -DServerName=unique vertical cluster servername -DWasPassword=password task, from the wp_profile_root/ConfigEngine directory, where unique vertical cluster servername is the name you specified when you created the cluster member.
   B. Restart the vertical cluster member referenced in the cluster-node-config-vertical-cluster-setup task.

5. Perform the following steps to access the Web Content Management content through an external Web server:
   A. Log on to the deployment manager administrative console.
B. Select **Environment > WebSphere Variables**.

C. From the **Scope** drop-down menu, select the `Node-nodename, Server-servername` option to narrow the scope of the listed variables, where `Node-nodename` is the node that contains the application server.

D. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router.

E. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router.

F. Perform the following steps to synchronize the node with the deployment manager:
   1. Select **System Administration > Nodes**.
   2. Select the node that you want to synchronize from the list.
   3. Click **Full Resynchronize**.

G. Log off of the deployment manager administrative console.

6. Save your changes and resynchronize the nodes.
   
   A. In the administrative console for the deployment manager, click **Save** on the task bar, and save your administrative configuration.
   
   B. Select **System Administration > Nodes**, select the node from the list, and click **Full Resynchronize**.

7. Stop and start the Web server.

**Parent topic:** Choosing the type of vertical cluster to create on Solaris
Tune your servers

Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris
  - **Base Portal Tuning Scenarios**

Tuning a WebSphere Portal environment involves tuning and configuring the various systems and components of the environment. The tuning guide provides general concepts and details specifics configuration instructions. Instructions are included for:

- Configuring the application server and the resources defined for that application server
- Determining the cloning strategy for expanding or extending the environment
- Tuning the database(s) and database server
- Tuning the directory server and its database
- Tuning the Web server
- Tuning the operating system and network
- Tuning the WebSphere Portal services

**Parent topic:** Setting up a cluster on Solaris

**Previous topic:** Preparing additional nodes on Solaris

**Next topic:** Configuring search in a cluster on Solaris

**Related information**
- WebSphere Portal and Lotus Web Content Management 6.1.x Performance Tuning Guide
- Tuning a Cluster Environment
- IBM WebSphere Portal Performance Troubleshooting Guide
Configuring search in a cluster on Solaris

IBM® WebSphere® Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris
  - Tune your servers

- **Configuring Portal Search in a cluster on Solaris**
  To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM WebSphere Application Server node that is not part of the IBM WebSphere Portal cluster.

- **Configuring JCR search in a cluster on Solaris**
  To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

**Parent topic:** Setting up a cluster on Solaris  
**Previous topic:** Tune your servers  
**Next topic:** Setting up multiple clusters on Solaris
Configuring Portal Search in a cluster on Solaris

To support Portal Search in a clustered environment, you must install and configure search for remote search service on an IBM® WebSphere® Application Server node that is not part of the IBM WebSphere Portal cluster.

To install and configure the search service remotely, perform the following tasks:

1. Install and configure the search service to work remotely, that is, on a remote WebSphere Application Server node which is not part of the portal cluster. You can provide the remote search service either as an EJB or as a Web service via SOAP. Deploy the appropriate EJB or SOAP EAR file on the remote WebSphere Application Server node. For details about how to do this, refer to the WebSphere Application Server documentation.

2. Configure the search portlets for remote search service so that they access the remote server accordingly.

Notes:

1. If you have configured a remote search service for a portal cluster, you need to configure the default location for search collections to a directory on the remote server that has write access.

2. The portal site default search collection is created only once at the first time when an administrator selects the search administration portlet Manage Search. If this occurred before you configure the portlet for remote search, then the default portal site search collection is only available on the primary node of the cluster, but not on the remote server. In this case you need to recreate the portal site collection to make it available for search on all nodes of the cluster.
Configuring JCR search in a cluster on Solaris

To enable search in a cluster for content stored in the JCR database, you must configure each server in the cluster to access a shared directory. JCR-based content includes content created with Web Content Management or Personalization.

Create a shared directory called `jcr/search` on a server in the network and ensure that each node in the cluster and the Deployment Manager has network access to the directory.

**Note:** If you are creating content in a clustered environment using the authoring portlet provided with Web Content Management, additional configuration steps are required to enable content created by these content features to be searchable in a cluster.

Perform the following steps on each server in the cluster to configure Search in a clustered environment:

1. **Edit the** `icm.properties` **file, located in the** `wp_profile_root/PortalServer/jcr/lib/com/ibm/icm` **directory.**
2. **Change the value of the** `jcr.textsearch.indexdirectory` **property to the shared directory; for example,**
   
   ```bash
   jcr.textsearch.indexdirectory=\\your_server\your_share\jcr\search
   ```

   You can specify the shared directory value in one of the following formats: *Table 1. The format for the shared directory.*

<table>
<thead>
<tr>
<th>Format</th>
<th>Shared directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal Naming Convention (UNC) format</td>
<td><code>\\your_server\your_share\jcr\search</code></td>
</tr>
<tr>
<td>Example:</td>
<td><code>\\hostname.example.com\share\jcr\search</code></td>
</tr>
<tr>
<td>Mounted resource format (with forward slashes)</td>
<td><code>/your_share/jcr/search</code></td>
</tr>
<tr>
<td>Example:</td>
<td><code>/mnt/jcr/search</code></td>
</tr>
</tbody>
</table>

   **Important:** This format requires that you mount the shared directory to the local server (for example, through a mapped network drive or a mounted directory). When using the mounted resource format, always use forward slashes instead of back slashes, regardless of the native operating system path format.

3. **Required:** Perform the following steps to delete the default search collections from the Manage Search portlet:
   
   A. Log on to WebSphere Portal as an administrator.
   B. Click **Administration > Search Administration > Manage Search.**
   C. Click **Search Collections.**
   D. Click the **Delete Collection** icon for the **Portal Content** search collection.
   E. Click **OK.**
   F. Restart the WebSphere_Portal server.
   G. Go to the Manage Search portlet and confirm that the **Portal Content** search collection was deleted.

**Parent topic:** Configuring search in a cluster on Solaris
Setting up multiple clusters on Solaris

The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM® WebSphere® Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

Before attempting alternative approaches for building multiple portal-based clusters within a single cell, please contact IBM.

- Prerequisites
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris
  - Tune your servers

- Installing multiple clusters in a single cell on Solaris
  Create a new, independent IBM WebSphere Portal cluster in a cell where a WebSphere Portal cluster already exists.

- Routing requests across clusters on Solaris
  The HTTP Server plug-in that comes with IBM WebSphere Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

Parent topic: Setting up a cluster on Solaris
Previous topic: Configuring search in a cluster on Solaris
Next topic: Sharing database domains between clusters on Solaris
Installing multiple clusters in a single cell on Solaris

Create a new, independent IBM® WebSphere® Portal cluster in a cell where a WebSphere Portal cluster already exists. In the following steps, Cluster A will be used to describe the existing cluster. Portal B will be used to describe the new server profile that will be the basis for the new cluster definition, Cluster B. Perform the following steps to install multiple clusters in a single cell:

1. Upgrade Cluster A, including the Deployment Manager node, to the current, supported hardware and software levels and to the current version of IBM WebSphere Portal.
2. Install and configure Portal B; see the "Preparing the primary node" topic for the appropriate operating system for details. Important: Maintain the same number of data sources with identical names to the Cluster A data sources so that data source bindings in the applications can be resolved on every cluster in which they run. If implementing database sharing across the clusters, the above statement refers to both the shared and non-shared domains; all domains should use the same names.
3. Optional: Using the same database user ID and password for each identically named domain/data source will allow the existing JAAS Authentication Aliases to be functional. If unique database user ID and password are required, additional manual configuration is needed to create new JAAS Authentication Aliases for each data source and map these accordingly. On the primary node of Cluster A, run the ./ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=dmgr_password task from the wp_profile_root/ConfigEngine directory to create the new JAAS Authentication Aliases. where authDomainList is set to a list of domains which use unique database user ID and passwords and those domain properties are set correctly in the wkplc_comp.properties file, including user ID and password.
4. Optional: If necessary, upgrade Portal B to the current cumulative fix.
5. Run the ./ConfigEngine.sh mapped-app-list-create -DWasPassword=password task from the wp_profile_root/ConfigEngine directory to build an inventory list of Portal B enterprise applications and portlets.
6. Stop the server1 and WebSphere_Portal servers on Portal B and ensure that the following parameters are set correctly in the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory:
   - Set WasSoapPort to the deployment manager's port.
   - Set WasRemoteHostName to the full host name of the deployment manager.
7. If the Deployment Manager is configured to use a stand-alone LDAP user registry, update the wkplc.properties file, located in the wp_profile_root/ConfigEngine/properties directory, on the primary node with the stand-alone LDAP user registry property values from the Deployment Manager. You can find these settings under the VMM Stand-alone LDAP configuration heading. Important: Ensure that you set WasUserId and WasPassword to the Deployment Manager user ID and password.
8. Run the ./ConfigEngine.sh cluster-node-config-pre-federation -DWasPassword=password task, from the wp_profile_root/ConfigEngine of the primary node.
9. Run the ./ConfigEngine.sh map-apps-to-server -DWasPassword=password task to determine which applications from the inventory list are no longer mapped to Portal B. The task uses the application profiles already in the cell to restore the mappings. Wait 30 minutes after running this task to allow all EAR files to expand before proceeding to the next step.
10. Perform the following steps to federate Portal B into the deployment manager cell:
    A. Ensure that all database parameters are correctly set, including passwords, in the wkplc_comp.properties and wkplc_dbtype.properties files.
B. Run the `./ConfigEngine.sh cluster-node-config-post-federation -DWasPassword=dmgr_password` task.

C. After running the `cluster-node-config-post-federation` task, wait at least 30 minutes to allow all EAR files to expand.

D. Since the WebSphere Portal node is now using security settings from the Deployment Manager cell, you need to update the WebSphere Portal administrative user ID and password to match an administrative user defined in the cell’s user registry. Run the `./ConfigEngine.sh wp-change-portal-admin-user -DWasPassword=password -DnewAdminId=newadminid -DnewAdminPw=newpassword -DnewAdminGroupId=newadmingroupid` task, from the `wp_profile_root/ConfigEngine` directory, to update the WebSphere Portal administrative user ID if the Deployment Manager cell is using a different user registry.

Additional parameter for stopped servers: This task verifies the user against a running server instance. If the server is stopped, add the `-Dskip.ldap.validation=true` parameter to the task to skip the validation.

Important: If standalone LDAP security is already enabled on the Deployment Manager cell, delay running the `wp-change-portal-admin-user` task until after the `cluster-node-config-cluster-setup` (static cluster) or `cluster-node-config-dynamic-cluster-setup` (dynamic cluster) task completes. After running the `wp-change-portal-admin-user` task, start or restart the WebSphere Portal server to use the updated administrator user ID.

Note: The WebSphere Portal administrative user ID and administrative group must exist in the Deployment Manager before running the `wp-change-portal-admin-user` task. `-DnewAdminPw` is an optional parameter to update the Administrative password in the wkplc.properties file if required.

E. From the administrative console, click System Administration > Node Agents.

F. Check the box next to the required node agent and then click Restart.

G. Stop and restart the deployment manager.

H. Stop and restart the WebSphere Portal server on Portal B

11. Restart the WebSphere Portal server on Cluster A. Verify that Cluster A is functionally intact by spot checking pages and portlets and then verify that Portal B is functionally intact by spot checking pages and portlets that you deployed into Portal B before it was federated. Any discrepancies or errors should be corrected now before continuing. Note: If Portal B is using a non-default Portal server administrative ID, not wpsadmin, the server will not be functional until the cluster configuration is complete and the Portal administrative ID has been configured to match the Cells security settings.

12. Choose one of the following options to define a cluster using Portal B as the basis:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
Perform the following steps to define a static cluster using Portal B as the basis: Run the 
`./ConfigEngine.sh cluster-node-config-cluster-setup -DWasPassword=dmgr_password`
task. Configure the cluster to use an external Web server to take advantage of features such as workload management. Choose one of the following options: Configuring a Web server and an application server on separate machines (remote) Configuring a Web server and an application server profile on the same machine Configuring a Web server and a deployment manager profile on the same machine

**Note:** Start with the step about launching the Plug-ins installation wizard. Perform the following steps to access the Web Content Management content through an external Web server: Log on to the deployment manager administrative console. Select Environment > WebSphere Variables. From the Scope drop-down menu, select the Node=nodename, Server=servername option to narrow the scope of the listed variables, where Node=nodename is the node that contains the application server. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere_Portal servers. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information: Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Perform the following steps to define a dynamic cluster using Portal B as the basis:

Log on to the deployment manager administrative console.

Perform the following steps to create a node group:

Click **New**. Type the node group **Name**. Type any information about the node group in the **Description** text box. Click **OK**. Click the **Save** link to save your changes to the master configuration.

Perform the following steps to add members to the node group:

Click **System administration > Node groups**. Click on the name of the node group that you want to add members to. Click **Node group members** under **Additional Properties**. Click **Add**. Select the primary node and then click **Add**. Click the **Save** link to save your changes to the master configuration.

Perform the following steps to create a dynamic cluster in the node group:

Click **Servers > Dynamic clusters**. Click **New**. Select WebSphere Application Server from the **Server Type** pull-down menu and then click **Next**. Type the cluster name in the **Dynamic cluster name** text box and then click **Next**. Type the same value that you provided for the **ClusterName** parameter in the **wkplc.properties** file of your primary node.

Remove all default membership policies and then click **Subexpression builder**. Enter the following information in the Subexpression builder window:

- Select **Logical operator** pull-down menu.
- Select **Nodegroup** from the **Select operand** pull-down menu.
- Select **Equals (=)** from the **Operator** pull-down menu.
- Type the nodegroup name you created in the previous step in the **Value** text box. Click **Generate subexpression**. Click **Append**.
- Click **Preview membership** to verify that all nodes included in the nodegroup display and then click **Next**. Click the **Create the cluster member using an existing server as a template** radio button and then select the WebSphere_Portal server for the primary node from the pull-down menu. Click **Next**. Specify the dynamic cluster properties and then click **Next**.
- Review the summary page to verify your actions and then click **Finish**.

Define or verify the following parameters in the **wkplc.properties** file, located in the **wp_profile_root/ConfigEngine/properties** directory:

- Set **ClusterName** to the name of the new dynamic cluster.
- Verify that **CellName** is set to the deployment manager cell.
- Verify that **NodeName** is set to the local WebSphere Portal node.
- Set **ServerName** to the server that will be used for the dynamic cluster member on this node.
- Verify that **PrimaryNode** is set to true.

Run the **. /ConfigEngine.sh cluster-node-config-dynamic-cluster-setup - DWasPassword=dmgr_password** task from the **wp_profile_root/ConfigEngine** directory to create the dynamic
13. Install any additional nodes to the cell to support additional cluster members for **Cluster B** identically to the primary node, and then federate as them as secondary nodes and define as cluster members on these nodes. For information about adding additional nodes navigate to **Installing WebSphere Portal > Setting up WebSphere Portal > Setting up a clustered production environment**. Select **Environment > WebSphere Variables**. From the **Scope** drop-down menu, select the **Node=nodename, Server=servername** option to narrow the scope of the listed variables, where **Node=nodename** is the node that contains the application server. Update the **WCM_HOST** variable with the fully qualified host name used to access the WebSphere Portal server through the Web server or On Demand Router. Update the **WCM_PORT** variable with the port number used to access the WebSphere Portal server through the Web server or On Demand Router. Save your changes and then restart the deployment manager, the node agent(s), server1, and the WebSphere Portal servers. If you are using a Web server to connect to the On Demand Router (ODR), configure the web server as a trusted proxy on the ODR. Refer to **Configuring a Web server as a trusted proxy server** for instructions. **Tip:** You can also configure the ODR to dynamically update the Web server configuration when changes occur. Refer to **Configuring an on demand router to dynamically update the Web server plug-in configuration** for instructions. Change the task list settings to point to the cluster instead of a single server if using Portal business process integration. See one of the following sections in the Information Center for information: **Cross cell: Adding a BPI-enabled portal server to a managed cell in a cross-cell setup** **Single cell: Adding a BPI-enabled portal server to a managed cell in a single-cell setup**

14. Restart the server1 and WebSphere_Portal servers on **Cluster A** and **Cluster B**.

15. If you entered passwords in any of the properties files while creating your cluster, you should remove them for security purposes. See “Deleting passwords from properties files” under Related tasks for information.

Installation of **Cluster B** is complete. It is now an independent cluster from **Cluster A**, which means that **Cluster B** can have its own configuration, set of end-user portlets, and target community. Any applications that are common between **Cluster A** and **Cluster B** are most likely infrastructure or related to administration, and special care needs to be taken to preserve their commonality between clusters and correct maintenance levels.

Adding a BPI-enabled portal server to a managed cell in a cross-cell setup
Adding a BPI-enabled portal server to a managed cell in a single-cell setup
Routing requests across clusters on Solaris

The HTTP Server plug-in that comes with IBM® WebSphere® Application Server is typically used to balance requests for applications across members of the cluster. While an application can be mapped to more than one cluster, automatic plug-in generation does not provide routing or balancing traffic for the same application across multiple clusters. Multiple cluster environments with shared applications therefore cannot rely solely on WebSphere Application Server automatic plug-in generation to be able to route requests using a web server. One option in this scenario is developing a customized method for defining and maintaining the plug-in configuration file used by the Web server to provide for the required routing of user requests.

An important consideration in a multiple cluster environment is ensuring that all subsequent HTTP requests for an end user are routed to the same cluster that processed the first HTTP request. The WebSphere Portal login processing depends upon preserving this cluster affinity during this initial time until the user has successfully logged in and session cookies maintain affinity. In order to guarantee that affinity is preserved during login, set the Navigator Service `public.session` parameter to a value of true. Refer to “Portal Configuration Services” for information on how to configure this parameter.

**Parent topic:** Setting up multiple clusters on Solaris
Sharing database domains between clusters on Solaris

To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM® WebSphere® Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Solaris
  - Preparing your Solaris operating system
  - Preparing the primary node on Solaris
  - Tune your servers

**Important:** JCR domains and release domains cannot be shared between different Web Content Management clusters or servers. Each distinct cluster or server in your Web Content Management system must use a separate JCR or release domain. For example:

<table>
<thead>
<tr>
<th>Development Server</th>
<th>Authoring Cluster</th>
<th>Staging Server</th>
<th>Delivery Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>JCR Domain 1</td>
<td>JCR Domain 2</td>
<td>JCR Domain 3</td>
<td>JCR Domain 4</td>
</tr>
<tr>
<td>Release Domain 1</td>
<td>Release Domain 2</td>
<td>Release Domain 3</td>
<td>Release Domain 4</td>
</tr>
</tbody>
</table>

Perform the following steps to share database domains when setting up an environment with multiple clusters:

1. Set up the first cluster (referred to as Cluster A in these instructions).
2. Determine which database domains you want to share with any other clusters in the environment.
3. Install the primary node of the next cluster (Cluster B), and perform the following steps to configure the node to use the shared database domains.
   A. Perform a partial database transfer of the database domains that you are not sharing. For example, if you are sharing only the Customization and Community domains, you would transfer the remaining domains to the database you are using for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to those domains from Cluster B.
4. Continue setting up the primary node as described in the cluster instructions.
5. Install the secondary node of Cluster B, and perform the following steps to configure the node to use the shared database domains.
   A. For those database domains that you are not sharing between clusters, reconfigure the domains to connect to the database domains you are using for Cluster B. As in the example for the primary node, if you are sharing only the Customization and Community domains, reconfigure the remaining domains on the secondary node to use the domains of the primary node for Cluster B.
   B. Reconfigure the shared database domains on the node to connect to the shared database domains you are using for Cluster A. For example, to connect to the Customization and Community domains for Cluster A, you would connect to
6. Continue setting up the secondary node as described in the cluster instructions.

Connecting to existing database domains
Setting up a cluster on Windows

In a production environment, you can install and configure IBM® WebSphere® Portal on a single (primary) node and then add additional nodes in the future as your company's needs grow. You can also deploy a high availability production environment by creating and configuring clustered deployments of multiple servers running WebSphere Portal managed by IBM WebSphere Application Server Network Deployment.

- Prerequisites
  - [Technotes for installation and configuration issues](#)

Perform the following steps to set up your production environment on Windows:

1. **Preparing prerequisite and corequisite software on Windows**
   Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

2. **Preparing your Windows operating system**
   View information on setting up your operating system for IBM WebSphere Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

3. **Preparing the primary node on Windows**
   Before creating your high availability environment, you must install IBM WebSphere Portal on your primary node and then configure your database and your network deployment manager.

4. **Choosing the type of cluster to create on Windows**
   If you installed a IBM WebSphere Application Server Network Deployment, create a static cluster to handle failover requests. If you installed a IBM WebSphere Virtual Enterprise, create a dynamic cluster to balance member workloads.

5. **Preparing a remote Web server when portal is installed on Windows**
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

6. **Configuring WebSphere Portal to use a user registry on Windows in a clustered environment**
   Configure user registry security on IBM WebSphere Portal to protect your server from unauthorized users. You can configure a stand-alone LDAP user registry or you can add LDAP user registries and/or database user registries to the default federated repository. After configuring your user registry, you can add realms for Virtual Portals or a lookaside database to store attributes that cannot be stored in the LDAP user registry.

7. **Preparing additional nodes on Windows**
   After installing and configuring your primary node, you can create your secondary nodes. You must install IBM WebSphere Portal on each node and then configure the node to access the database and user registry before adding it to the cluster.

8. **Tune your servers**
   Tuning the servers is important to the performance of your WebSphere Portal environment. WebSphere Portal is not tuned for a production environment out of the box, so to ensure optimal performance, review and complete the steps in the IBM WebSphere Portal Tuning Guide. Even if a tuning guide is not available for the current release of WebSphere Portal, the tuning guide for the previous product version should be used.

9. **Configuring search in a cluster on Windows**
   IBM WebSphere Portal provides two distinct search capabilities. You can utilize both types of search capabilities in a clustered environment.
10. **Setting up multiple clusters on Windows**

   The majority of the steps to build another cluster are the same as when building the first cluster in the same cell, with a few exceptions. Basically, the new profile will be designated as the primary profile, using IBM WebSphere Portal clustering terminology, and will then be used as the basis for the new cluster definition. This duplicates the build process of the first cluster in the cell. During the federation process, if any applications on this new node already exist in the cell (because they are in use by the first cluster), then Deployment Manager will not allow them to be added. After federation, the applications that already exist in the cell are not mapped to the WebSphere_Portal server on the newly federated node, and thus the existing applications must be remapped to this newly federated server to restore its application list. Therefore, depending on the configuration of the new profile, there will likely be some combination of applications shared with the other existing cluster, and some applications unique to this new profile.

11. **Sharing database domains between clusters on Windows**

   To help provide redundancy and failover support in production environments composed of multiple clusters in a single cell and multiple clusters in different cells, you can share database domains between those clusters. IBM WebSphere Portal data is organized into different database domains, with different availability requirements depending on how the production environment is set up. When multiple lines of production are involved and each line of production is implemented as a cluster of servers, sharing database domains ensures that the data is automatically synchronized across the lines of production.

Preparing prerequisite and corequisite software on Windows

Before creating your high availability production environment, you must prepare your database, your user registry, your deployment manager, and your remote Web server.

Perform the following tasks to prepare prerequisite and corequisite software:

1. Preparing the WebSphere Application Server Deployment Manager on Windows
   IBM WebSphere Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

2. Preparing a remote Web server when portal is installed on Windows
   Install and configure the Web server plug-in, provided by IBM WebSphere Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

Parent topic: Setting up a cluster on Windows
Next topic: Preparing your Windows operating system
Preparing the WebSphere Application Server Deployment Manager on Windows

IBM® WebSphere® Portal provides a customized installation package (CIP) that includes IBM WebSphere Application Server Network Deployment and all required maintenance packages. Use the supplied discs to install WebSphere Application Server Network Deployment on a dedicated system.

Perform the following steps to prepare the WebSphere Application Server Deployment Manager:

1. Install WebSphere Application Server Network Deployment or use the CIP to upgrade an existing installation. Run the following command:
   ```markdown
cd_root\windows\ia32\ifpackage\WAS\install.exe
or
cd_root\windows\amd64\ifpackage\WAS\install.exe
```
   where `cd_root` is the root directory of the disc.

2. Choose one of the following options to create a default deployment manager profile:
   **Important:** While creating the default deployment manager profile, enable administrative security. If you use the Profile Management Tool, check the enable administrative security check box. If you use the manageprofile command, add the `-enableAdminSecurity=true` parameter to the command line.

   - **Profile Management Tool**
     See [Creating a deployment manager profile](#) for information.

   - **manageprofile commands**
     See [manageprofile commands](#) for information.
     **Note:** If you have a 64-bit environment, only the manageprofiles command is supported when creating profiles.

3. Run the following command to start the deployment manager: `startManager.bat`, from the `dmgr_profile_root\bin` directory.

4. Use the following URL to launch the network deployment administrative console:
   ```markdown
   http://dmgr_hostname:9060/ibm/console
   ```
   where `dmgr_hostname` is the fully qualified host name for the WebSphere Application Server Network Deployment.

5. Log into the deployment manager administrative console.

6. Increase the HTTP connection timeouts for the deployment manager.
   A. Click **System Administration > Deployment Manager > Web container transport chains**.
   B. Increase the timeout values. For the **WCInboundAdmin** and **WCInboundAdminSecure** entries listed in the web container transport chains section, complete the following steps to increase the timeout values:
      1. Click **HTTP Inbound Channel**.
      2. Change the **Read timeout** value to 180.
      3. Change the **Write timeout** value to 180.
      4. Save the configuration changes.

7. Change the timeout request period for the Java Management Extensions (JMX) connector.
   A. Click **System administration > Deployment Manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties**.
   B. Select the **requestTimeout** property, and increase the value from 600 to 6000.
   C. Save the configuration changes.

8. Update the maximum Java heap size used by the deployment manager:
   A. Click **System administration > Deployment manager > Java and Process Management > Process Definition > Java Virtual Machine**.
B. Update the value in the **Maximum Heap Size** field. For information about appropriate heap sizes see the documentation for your operating system in the Performance Guides located on the WebSphere Portal and Web Content Management Product Documentation page. **Note:** If using a 32-bit operating system, you will need to set the heap size to a lower size than a 64-bit operating system.

C. Click **OK** and then save your changes.

9. Depending on your version of WebSphere Application Server, make the appropriate selection from the navigation:

   **Note:** If security is not enabled on your deployment manager, see [Enabling security](#) for information before performing this step.

   - For **WebSphere Application Server Version 6.1**: Click **Security > Secure administration, applications and infrastructure** and select **Enable Application Security**. Then save the configuration changes.

   - For **WebSphere Application Server Version 7.0**: Click **Security > Global security** and select **Enable Application Security**. Then save the configuration changes.

10. Verify that the WebSphere Portal administrative users and administrative group exist in the Deployment Manager cell's user registry. Perform the following steps if you need to create the administrative users and group:

   A. Click **Users and Groups > Manage Users**.

   B. Click **Create**.

   C. Type the information for the WebSphere Portal administrative users; for example **wpsadmin** and **wpsbind**, and then click **Create**.

   D. Click **Users and Groups > Manage Groups**.

   E. Click **Create**.

   F. Type **wpsadmins** as the name of the WebSphere Portal administrative group and then click **Create**.

   G. Click the group you just created; for example **wpsadmins**.

   H. Click the **Members** tab.

   I. Click **Add Users**.

   J. Search for the users.

   K. Select the users you want to add to the group.

   L. Click **Add** to add the users to the group.

   M. Click **Close** when you are done adding users to the group.

   N. Log out of the administrative console.

11. Change the timeout request period for the Simple Object Access Protocol (SOAP) client. Edit the **soap.client.props** file, located in the **Dmgr_profile\properties** directory: Change the line to: **com.ibm.SOAP.requestTimeout=6000**.

12. Run the following tasks to stop and restart the deployment manager:

   A. **stopManager.bat** -username **admin_userid** -password **admin_password**, from the **dmgr_profile_root\bin** directory

   B. **startManager.bat**, from the **dmgr_profile_root\bin** directory

---

Parent topic: [Preparing prerequisite and corequisite software on Windows](#)

Preparing a remote Web server when portal is installed on Windows

Install and configure the Web server plug-in, provided by IBM® WebSphere® Application Server, to set up your Web server to communicate with IBM WebSphere Portal.

- Prerequisites

  - Preparing the WebSphere Application Server Deployment Manager on Windows
  - Preparing prerequisite and corequisite software on Windows
  - Preparing your Windows operating system
  - Preparing the primary node on Windows

Perform the following steps to install and configure your Web server:

1. Install and configure the Web server; refer to the Web server documentation for information.

2. If using Microsoft Internet Information Server, we recommend updating the `UrlSegmentMaxLength` Registry key to a value of 0 to eliminate potential problems in a WebSphere Portal environment with the default IIS limitation on the length of URL path segments. We also recommend updating the `AllowRestrictedChars` Registry key to a value of 1 to accept hex-escaped characters in request URLs that decode to the U+0000 - U+001F and U+007F - U+009F ranges. **Note:** Refer to `Http.sys registry settings for IIS` for information.

3. If using IBM Lotus® Domino®, edit the `NOTES.INI` file on the Web server. Set the `HTTPEnableConnectorHeaders` parameter to 1.

4. If using IBM HTTP Server or Apache Server, edit the `httpd.conf` file on the Web server. Set the `AllowEncodedSlashes` directive to `on`; the directive should be added at the root level as a global directive.

5. Stop the Web server.

6. Install and configure the Web server plug-in on the system where the Web server is located using the Plug-ins installation wizard provided with WebSphere Application Server. Refer to `Selecting a Web server topology diagram and roadmap` for information. **Note:** The WebSphere Application Server Web server instructions are for the default profile. If not using the default profile, refer to `Configuring a Web server for a non-default profile`.

   **If using WebDAV:** After successfully installing the Web server plug-in, locate and open your `plugin-cfg.xml` file and set `AcceptAllContent` to `true`.

   **Important:** Depending on how you use the Web server, you may need to adjust the `ServerIOTimeout` value, which defines how long the plug-in should wait for a response from the application. The recommended minimum value is 60 but you may need to adjust this value higher if you are retrieving data from a database. To update this value, locate and open your `plugin-cfg.xml` file and set `ServerIOTimeout` to a value that is appropriate for your business needs. For additional information, see `Common questions about the Web server plug-in`.

7. If you are using Sun Web Server Version 7 update 8, read Technote 1448262 and perform the steps to resolve the HTTP 408/409 error.

8. Start the Web server.

**Parent topic:** Preparing prerequisite and corequisite software on Windows
Preparing your Windows operating system

View information on setting up your operating system for IBM® WebSphere® Portal. Other components might require additional steps; see the product documentation for the specific components you want to install for information.

- Prerequisites
  - Preparing prerequisite and corequisite software on Windows

Perform the following steps to prepare your operating system:

1. Check that the system logon user ID you will use during installation has the following permissions and rights:
   - The user ID must already exist prior to installation.
   - The user ID must belong to the Administrators group.

2. Perform the following steps to determine if a user account is a member of the Administrators group:
   A. Click Start > Programs > Administrative Tools > Computer Management.
   B. Expand Local Users and Groups and select Groups.
   C. Open the Administrators group to see what members belong to it.
   D. Add the user to the Administrators group if necessary.

3. Consider the following recommendations when installing to avoid excessively long path names: Note: If you exceed the 259 maximum character length, you may receive one of the following error messages during configuration or in the wpinstalllog.txt file:
   - The input line is too long.
   - The syntax of the command is incorrect.
   - The filename is too long.

   A. Use a short installation path. For example, use C:\WebSphere instead of C:\Program Files\IBM\WebSphere.
   B. Specify node names; do not use names longer than 5 characters. For example, you might use node1 instead of longnodename01.
   C. Name WAR files with less than 21 characters. If necessary, modify the file name before installing.

Parent topic: Setting up a cluster on Windows
Previous topic: Preparing prerequisite and corequisite software on Windows
Next topic: Preparing the primary node on Windows
Preparing the primary node on Windows

Before creating your high availability environment, you must install IBM® WebSphere® Portal on your primary node and then configure your database and your network deployment manager.

- **Prerequisites**
  - Preparing prerequisite and corequisite software on Windows
  - Preparing your Windows operating system

Perform the following tasks to prepare your primary node:

1. **Installing WebSphere Portal on Windows on the primary node**
   IBM WebSphere Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

2. **Configure WebSphere Portal to use a remote database**
   For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

3. **Configuring the primary node to communicate with the deployment manager on Windows**
   After installing IBM WebSphere Application Server Network Deployment and installing IBM WebSphere Portal on the primary node, you must configure the primary node and the deployment manager to communicate with each other.

4. **Removing search collections on Windows**
   If you plan to use search in a cluster, you must configure a remote search server; see Configuring Portal Search in a cluster for information. If you created any search collections, you will need to recreate them on the remote search server. If your search collection has data, export the collection before deleting it and then import the data on the remote server.

**Parent topic:** Setting up a cluster on Windows  
**Previous topic:** Preparing your Windows operating system  
**Next topic:** Choosing the type of cluster to create on Windows
Installing WebSphere Portal on Windows on the primary node

IBM® WebSphere® Portal is installed as a single component, complete with an integrated database for storing information. This allows you to get WebSphere Portal up and running quickly for a proof of concept phase where you can immediately begin building and working with it. You can also expand your environment to include high availability failover, a more robust database, and LDAP-based authentication.

Review the Supported hardware and software requirements for your operating system and ensure that all hardware and software matches the minimum product level before installing WebSphere Portal. Review Installation methods, options, and sources before installing to determine your installation source location and installation method.

Perform the following steps to install WebSphere Portal and create a custom profile for the node that will be added to the cluster. If you already installed WebSphere Portal, you can skip to the last step to create the custom profile.

1. Type `ping yourserver.yourcompany.com` on a command line to verify that your fully qualified host name is properly configured.
2. Type `ping localhost` on a command line to verify that your network is properly configured.
3. If you are installing with an existing WebSphere Application Server instance, ensure it is installed at the supported level and has the following features installed:
   - Application Server
   - Administration
     - Scripted Administration
     - Administrative Console
   - Ant and Deployment Tools
     - Deploy Tool
     - Ant Utilities
   - Important: Besides ensuring that the existing WebSphere Application Server instance is at the supported level, you will also need to ensure that Apache Derby is installed at the supported level before installing WebSphere Portal. See WebSphere Portal detailed system requirements for supported levels.

4. If you are installing on a server with a firewall, antivirus, and/or desktop search engine enabled, disable them before installing. If you do not disable them and the installation program detects them, a warning message displays during the installation.

5. Choose one of the following installation commands based on the installation method you want to use to install WebSphere Portal; see Installation Methods for more information:
   - **Advance installation parameters:** To customize your installation, you can add various parameters to your installation commands; for example, you can specify your port information. See Advanced installation parameters for information.
   - **Restriction:** When defining your installation path, the ONLY supported characters are ASCII letters [A-Z and a-z], numbers [0-9], slashes [/ or \, depending on your operating system], and the dash [-].

<table>
<thead>
<tr>
<th>Table 1. Installation task options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Installation type</strong></td>
</tr>
</tbody>
</table>

1993
6. Verify your installation was successful; access WebSphere Portal using the `http://yourserver:yourport/wps/portal` format. Run the `ConfigEngine.bat list-server-ports -DWasPassword=password` task from the `wp_profile_root\ConfigEngine` directory to generate the `wp_profile_root\ConfigEngine\log\wp_PortMatrix.txt` file that lists the WebSphere Portal ports for your installation.

7. Optional: After the WebSphere Portal installation completes successfully, run the `ConfigEngine.bat configure-express -DPortalAdminPwd=password -DWasPassword=password` task, from the `wp_profile_root\ConfigEngine` directory, if you want to enable the sample IBM Lotus Web Content Management content, such as internet and intranet sample sites.

   **Restriction:** Run the `configure-express` task before configuring your database, user registry, context root, security, etc. If you ran any tasks other than the install task, do not run this task.

   The sample content includes: **Note:** See [http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html](http://publib.boulder.ibm.com/infocenter/wpexpdoc/v6r1m0/topic/com.ibm.wp.exp.doc/wcm/wcm_jumpstart_ovw.html) for tutorials on how to use the sample content.

   - Creates a group called `contentAuthors`; members of this group are given privileges to create content in the sample Internet and intranet sites. Navigate to the **Administration** area and then click **Access > Users and Groups**.
   - Creates two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0". Navigate to the **Administration** area and then click **Portal Content > Web Content Libraries**.
   - Adds a portlet filter and applies the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the **Environment** area.
   - Creates two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to **Theme Customizer** and then select the style.
   - Creates several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites.
   - Creates several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the

---

**Note:** If the installation program does not detect a WebSphere Application Server instance that you know exists, exit the installation program and pass the WebSphere Application Server instance location using the command line; for example, `install.bat -W was.undetectedWas="/my/WAS/location"`. **Note:** If the GUI or console mode installation program fails to detect ports for either WebSphere Application Server or WebSphere Portal, a warning message displays and the installer offers another chance to enter the values. If the silent installation fails to detect ports for either WebSphere Application Server or WebSphere Portal, the installer will exit.

**Note:** To use the sample content, you need to create a group called `contentAuthors`; members of this group are given privileges to create content in the sample Internet and intranet sites. Navigate to the **Administration** area and then click **Access > Users and Groups**. Then, create two new Web Content Management Libraries: "Internet Web Content 6.1.0" and "Intranet Web Content 6.1.0". Navigate to the **Administration** area and then click **Portal Content > Web Content Libraries**. Add a portlet filter and apply the filter to various portlets in the sample Internet and intranet sites. You can see the definition of the filter in the WebSphere Application Server Administration console and examining the custom resources under the **Environment** area. Create two new theme policies: InternetStyle and IntranetStyle. These styles are applied to sample Internet and intranet sites. Navigate to **Theme Customizer** and then select the style. Create several portlet clones of the Web Content Management rendering portlet. These portlet clones are used on sample Internet and intranet sites. Create two virtual portals with context roots of `wps/portal/intranet` and `wps/portal/internet`. These are the sample Internet and intranet sites. Go to [http://yourserver:yourport/wps/portal/internet](http://yourserver:yourport/wps/portal/internet) and [http://yourserver:yourport/wps/portal/intranet](http://yourserver:yourport/wps/portal/intranet) to access them. Create several sample credential slots, including "Default slot for E-mail", "Default slot for Feeds", "Default slot for Miscellaneous", "Default slot for Web Clipping", and "Default slot for Web Content Management". Navigate to the...
Administration area and then click Access > Credential Vault > Manage System Vault Slots.
- Modifies the portlet palette to include some new portlets. Click the Portlets link to see the portlet palette.

8. Optional: If you ran the configure-express task, the owner of the items in the Web content libraries containing the Internet and Intranet Site Template content will be listed as uid=xyzadmin,o=defaultWIMFileBasedRealm. To update the owner information for these items to correspond to your portal administrator ID, complete the following steps:

A. Edit the wp_profile_root\PortalServer\wcm\shared\app\config\wcmservices\MemberFixerModule.properties file.
B. Add the following line to the file:
   
   `uid=xyzadmin,o=defaultWIMFileBasedRealm -> portal_admin_DN`
   
   Replace `portal_admin_DN` with the distinguished name of the portal administrator.
C. Save your changes and close the file.
D. Run the ConfigEngine.bat action-express-memberfixer -DPortalAdminPwd=yourpassword -DWasPassword=yourpassword task, located in the wp_profile_root\ConfigEngine directory.

9. Optional: Perform the following steps if you need to change the ports for WebSphere Application Server or WebSphere Portal:

   **Note:** The starting port parameter is required for a successful completion of the modify-ports-by-startport task.

   Once you specify a start port, this port becomes the base for assigning port values. The code increments this value as each port is assigned, which means that the WebSphere Portal ports will be assigned incrementally starting with the port defined with the modify-ports-by-startport task.

   A. Stop the server1 and WebSphere_Portal servers.
   B. Run one of the following commands for each server you need to change:

<table>
<thead>
<tr>
<th>Method</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting port number</td>
<td>ConfigEngine.bat modify-ports-by-startport -DWasPassword=password -DModifyPortsServer=servername -DStartPort=starting port number</td>
</tr>
</tbody>
</table>

   The following is an example of the information within a port file although the port values will be different based on your environment:

   ```
   BOOTSTRAP_ADDRESS=10031
   SOAP_CONNECTOR_ADDRESS=10033
   SIB_MQ_ENDPOINT_ADDRESS=10030
   SIB_MQ_ENDPOINT_SECURE_ADDRESS=10037
   SIB_ENDPOINT_ADDRESS=10026
   SIB_ENDPOINT_SECURE_ADDRESS=10037
   ```

C. Restart the server1 and WebSphere_Portal servers.

Configure WebSphere Portal to use a remote database

For high availability, using a remote database is preferred. For improved performance databases can be distributed across multiple database servers. Databases should also be configured for failover. Configuring the database for failover is beyond the scope of this documentation. Refer to the database product documentation for the most authoritative guidance about setting up databases for fail over.

Password considerations when transferring data manually

For security reasons, you should not store passwords in the wkplc.properties and wkplc_comp.properties. Edit each of the properties files prior to running a configuration task, inserting the passwords needed for that task. After the task has run, delete all passwords from each file. For more information, see Deleting passwords from configuration scripts. Alternatively, you can specify the password on the command line using the following syntax:

- Windows: ConfigEngine.bat task_name -Dpassword_property_key=password_value
- UNIX: ./ConfigEngine.sh task_name -Dpassword_property_key=password_value
- i5/OS: ConfigEngine.sh task_name -Dpassword_property_key=password_value

As with other properties, each password property must have the -D prefix and be set equal to (=) a value. If you have multiple properties in a single command, use a space character between each -Dproperty=value setting.

- Prerequisites

  - Installing WebSphere Portal on Windows on the primary node
  - Technotes for database connectivity issues

- Configuring WebSphere Portal to use DB2

  View information on installing and setting up DB2 to work with WebSphere Portal.

- Configuring WebSphere Portal to use DB2 for z/OS

  View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle

  View information on installing and setting up Oracle to work with WebSphere Portal.

- Configuring WebSphere Portal to use Oracle RAC

  View information on installing and setting up Oracle RAC to work with WebSphere Portal.

- Configuring WebSphere Portal to use SQL Server

  View information on installing and setting up SQL Server to work with WebSphere Portal.

- Verifying databases

  After you configure IBM WebSphere Portal to work with your database, test the database connection to ensure that it operates correctly. Then verify that all database transactions work properly within the WebSphere Portal environment. For example, all portal pages should display without HTTP 404 errors, and there should be no database layer-related exceptions in the SystemOut.log and SystemErr.log files.

Troubleshooting WebSphere Portal Version 6.1 databases
Configuring WebSphere Portal to use DB2

View information on installing and setting up DB2 to work with WebSphere Portal.

1. **Installing DB2**
   View information on installing DB2 for use with WebSphere Portal.

2. **Create users**
   View the steps to set up users for DB2 to work with WebSphere Portal.

3. **Creating remote databases**
   A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

4. **Optional: Assigning custom table spaces**
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

5. **Modifying database properties**
   Learn how to modify the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

6. **Optional: Configuring JCR collation support**
   View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

7. **Configuring WebSphere Portal to use DB2**
   View information on manually transferring data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

8. **Configuring DB2 for large file handling in Web Content Management**
   If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

9. **Optional: Changing driver types**
   WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing DB2
View information on installing DB2 for use with WebSphere Portal.

Before you begin:
- **(For Type 2 drivers only):** DB2 Connect must be installed on the same system as WebSphere Portal, and have the same name as the server profile name.
- When you install DB2 using the DB2 installation program, it automatically creates a DB2 administrative user with the correct operating system rights.

1. If you are using the JDBC driver in type 2 mode, configure your DB2 Connect client with the following commands. If you are using a remote database, complete this step separately from the WebSphere Portal installation.
   - `db2 update dbm cfg using tp_mon_name WAS`
   - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name of WebSphere Portal. Because the default for `spm_name` is the hostname itself, specifying the `hostname` parameter is optional. If your hostname is more than eight characters, use empty double quotes (" "). For example, `db2 update dbm cfg using spm_name " "`.

2. Before installing DB2, log in with a user ID that has administrative authority. This user should have the following specifications:
   - Belong to the local Administrator group
   - Act as part of the operating system
   - Have permissions to create a token object
   - Windows 2003 only: Have permissions to adjust memory quotas for a process
   - Have permissions to replace a process level token

   To edit user rights:
   - For the first two specifications: Click **Start > Programs > Administrative Tools > Computer Management > Local Users and Groups**.
   - For the last four specifications: Click **Start > Programs > Administrative Tools > Local Security Policy**. Then, click **Local Policies > User Rights Assignment**.

3. To install DB2, follow the instructions that are provided with the DB2 documentation to install DB2 and the required fix pack.

Parent topic: Configuring WebSphere Portal to use DB2
Next topic: Create users

Related Information
- **DB2 Technical Support**
- **DB2 Information Center**
Create users

View the steps to set up users for DB2 to work with WebSphere Portal.

Before you begin: You should have completed Installing DB2.

- **Prerequisites**
  - Installing DB2

For all databases, use one user with administrative rights on the operating system and the DB2 installation. This user can be the database administrative user that is created automatically by the DB2 installation program. This user is the database configuration user that will be used for configuration tasks: creating database tables and performing database transfer. If you choose to have WebSphere Portal also create the databases, the database user should be given SYSADM rights. You only need to manually create an administrator ID when you do not want to use an existing DB2 administrator ID.

A common user name is `db2inst1`, but you can assign any user name as long as it has administrative access and follows the limitations listed here. Do not change the user name after creating it.

The limitations on user names are:

- User names can contain one to 20 characters.
- Group and instance names can contain one to eight characters.
- Names cannot be any of the following: `users`, `admins`, `guests`, `public`, `local`.
- Names cannot begin with: `IBM`, `SQL`, `SYS`.
- Names cannot include accented characters.
- Create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Following are the basic steps to create new users and grant privileges. For more information, refer to the DB2 product documentation.

1. From the DB2 Control Center, expand the object tree until you find the DB Users folder.
2. Right-click the DB Users folder and select **Create/Add**. The Create DB User notebook opens.
3. In the User name field, type a user ID.
4. Assign an authority for the user.
5. Click **OK**.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Installing DB2  
**Next topic:** Creating remote databases
Related Information

DB2 product documentation
Creating remote databases

A remote database resides on a different system than WebSphere Portal. When you use a remote server, you must manually create the databases that are required by WebSphere Portal.

Before creating these databases, note the following information:

- Use IBM® DB2 Universal Database™ Enterprise Server Edition JDBC driver, JCC, type 4.
- If the DB2 JDBC type 4 driver is used, only the instructions on the remote server are required. You do not need to install the DB2 client software, and you do not need to complete the steps related to the DB2 client.
- The client software, DB2 Connect, must be correctly configured to connect to the remote DB2 server instance, for example, `db2inst1`.
- These instructions assume that a remote DB2 server and DB2 Connect are already installed and running. For information on installing DB2 Connect, see the DB2 product documentation.

**Prerequisites**
- Installing DB2
- Create users

To create a database, you must be a DB2 System Administrator with sufficient database privileges (SYSADM or at a minimum SYSCtrl).

1. Log in to the DB2 server system as a user with sufficient database privileges.
2. Ensure that the database user has been created, granted appropriate privileges, and has a password assigned to it. If the user has not been created, refer to the Creating users topic for information on how to create users.
3. Initialize a DB2 command environment by opening a command prompt and typing `db2cmd`. In this mode, you must type `db2` at the beginning of each command and use double quotation marks (`"`) around the entire command. The following example shows how to use the double quotes; it is not an actual command that you run:

   ```
   db2 "CREATE REGULAR TABLESPACE SMS PAGESIZE 4 K MANAGED BY SYSTEM USING ('sms') BUFFERPOOL SMSPOOL"
   ```

   **Note:** If you are using the Command Line Processor (CLP), refer to your DB2 documentation for details. The command prompt is `db2->`. In this mode, commands can be entered without the `db2` prefix or the double quotation marks.

   However, the following steps assume you are not using the CLP and are entering commands from the `$` prompt.

4. Run the following commands on the DB2 server system to configure the DB2 database instance:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Description</th>
</tr>
</thead>
</table>
| DB2         | `db2set DB2_RR_TO_RS=YES`  
|             | `db2set DB2_EVALUNCOMMITTED=YES`  
|             | `db2set DB2_INLIST_TO_NLJN=YES`  
|             | `db2 "UPDATE DBM CFG USING query_heap_sz 32768"`  
|             | `db2 "UPDATE DBM CFG USING maxagents 500"`  
|             | `db2 "UPDATE DBM CFG USING sheapths 0"`  

5. **(Important)** Failure to complete this step will result in an unsuccessful database transfer. Run the following commands on the DB2 server system to create the necessary databases:

   - Replace `dbname` with the actual name of the database. Run the commands and each time replace `dbname` with the actual values for release, community, customization, Java Content Repository, Feedback, and Likeminds. You will need to run the commands once for each database for a total of six times.

   **Remember:** DB2 database names cannot
exceed eight characters. Therefore, consider using these database names: release, commun, custom, jcrdb, fdbkdb, and lmdb.

```
6. Complete the following:

A. On the DB2 server system, run the following commands. This step is only required for the IBM Java Content Repository database (jcrdb).

- jcrdb is the name of the database used to store user data and objects
- jcr is the jcr user for jcrdb
- dbpassword is the password for the jcr user for the jcrdb

```
```
db2 "CREATE DB dbname using codeset UTF-8 territory us PAGESIZE 8192"
db2 "UPDATE DB CFG FOR dbname USING applheapsz 4096"
db2 "UPDATE DB CFG FOR dbname USING app_ctl_heap_sz 1024"
db2 "UPDATE DB CFG FOR dbname USING stmheap 32768"
db2 "UPDATE DB CFG FOR dbname USING dbheap 2400"
db2 "UPDATE DB CFG FOR dbname USING locklist 1000"
db2 "UPDATE DB CFG FOR dbname USING logfilsiz 4000"
db2 "UPDATE DB CFG FOR dbname USING logprimary 12"
db2 "UPDATE DB CFG FOR dbname USING logsecond 20"
db2 "UPDATE DB CFG FOR dbname USING logbufsz 32"
db2 "UPDATE DB CFG FOR dbname USING avg_appls 5"
db2 "UPDATE DB CFG FOR dbname using AUTO_MAINT off"
```
```
B. On the DB2 server system, check the services file. If it does not specify DB2 connection and interrupt service ports, specify the ports for your operating system: Use a text editor to open the file /etc/services and add the following text:
```
db2c_db2inst1port1/tcp
```
where db2inst1 is the default instance and port1 is the TCP port DB2 listens on. Replace port1 with the actual port
number that assigned to the DB2 connection service in your DB2 server installation.

The /etc/services file is located under %systemroot%/system32/drivers/, where %systemroot% is the location of the operating system. For example C:\Windows\system32\drivers\etc\services.

C. For JDBC Type 2 connections only: On DB2 Connect, use a text editor to open the /etc/services file. If it does not specify the DB2 connection service port, add the following text to specify the port for the remote DB2 instance:

db2c_db2inst1 port1 # DB2 connection service port

where db2inst1 is the name of the DB2 instance ID on the system, and port1 with the actual port number that is assigned to the DB2 connection service in your DB2 server installation. The connection service port on the DB2 Client system, WebSphere Portal server, must match the connection service port on the DB2 server. The ports should match by number but not necessarily by name.

D. Set up the correct service name by entering the following command on the DB2 server system:

db2 "UPDATE DBM CFG USING svcename svce_name" where svce_name is the connection service port name that is specified in substep b, such as db2c_db2inst1.

E. For JDBC Type 2 connections only: On DB2 Connect, set DB2COMM to TCP/IP by using the db2set command:

db2set DB2COMM=tcpip.

F. For JDBC Type 2 connections only: Catalog the TCP/IP node with the IP address of the remote database server on DB2 Connect:

db2 "catalog tcpip node remote_db_node_alias remote database_server_node_name connection_service_port" where:

- remote_db_node_alias is the alias name of the database server that you are defining for the WebSphere Application Server node name. The alias name can contain one to eight characters.
- database_server_node_name is the fully qualified host name of your database server system.
- connection_service_port is the name of the DB2 connection service port that is configured in the /etc/services file on the database server system.

G. For JDBC Type 2 connections only, catalog the WebSphere Portal databases on DB2 Connect, where:

- remote_db_name_domain, is the cataloged name of the databases on the server system for each domain.
- domain_alias_name, is the database alias names that you are defining.
- remote_db_node_alias is the name that was used previously when you cataloged the TCP/IP node in the previous step.

The alias for each database must be different from the actual database name and can only contain up to eight characters.

db2 "catalog db remote_db_name_release as release_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_community as comm_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_customization as cust_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_fdbkdb as fdbkdb_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_lmdb as lmdb_alias_name at node remote_db_node_alias"
db2 "catalog db remote_db_name_jcrdb as jcrdb_alias_name at node remote_db_node_alias"

H. For JDBC Type 2 connections only: Log out of DB2 Connect by entering db2 "terminate".

I. For JDBC Type 2 connections only, on DB2 Connect, test your remote connection by issuing the following command in the DB2 command window:

db2 "connect to alias_name user username using password", where alias_name is the alias name that you defined above, username is the database user, and password is the password assigned to the database user.
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- The page size of table spaces used by WebSphere Portal must be 8192 bytes.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**

- Installing DB2
- Create users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file `wp_profile_root`/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - `dbdomain.table_name.tablespace`
   - `dbdomain.table_name.index_name.indexspace`
   
   For the file name and each table space and index space property pair, `dbdomain` can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds

3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword `IN` and a space. For example: `community.COMP_INST.tablespace=IN COMM8KSPACE`
   
   Repeat this step for each domain that you are transferring.

4. Save and close `dbdomain.space_mapping.properties`.
5. From a command prompt, specify the option `-DuseCustomTablespaceMapping=true` when starting the database transfer. For example,
   - Windows: `ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true`
   - UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Creating remote databases  
**Next topic:** Modifying database properties
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data. Create a backup copy of each properties file before modifying it.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release(DbName)=release
  - jcr(DbName)=jcrdb
  - feedback(DbName)=fdbkdb
  - likeminds(DbName)=lmdb
  - community(DbName)=commdb
  - customization(DbName)=custdb

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds

- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment. Note: The wkplc_comp.properties file by default has the properties populated for the Apache Derby database. The source.dbdomain.properties represent the properties for the source database. These values should not be modified unless you are transferring from a supported database other than Apache Derby.

   A. For dbdomain.DbType, type db2.
   B. For dbdomain.DbName, type the name of the WebSphere Portal domain database. Note: This value is also the database element in the dbdomain.DbUrl property.
   C. For dbdomain.DbName, type the name of the WebSphere Portal domain database. DB2 database names cannot exceed eight (8) characters. Note: This value is also the database element in the dbdomain.DbUrl property.
   D. For dbdomain.DbSchema, type the schema name of the database domain. Note: Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand.
   E. For dbdomain.DataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback
   F. For dbdomain.DbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. Note: The database element of this value should match the value of DbName.
   G. For dbdomain.DbUser, type the user ID for the database administrator.
   H. For dbdomain.DbPassword, type the password for the database administrator.
   I. Optional: For dbdomain.DbRuntimeUser, type the user ID of the database user that should be used by WebSphere Portal to connect to the database at runtime.
   J. If dbdomain.DbRuntimeUser is specified, you must set dbdomain.DbRuntimePassword to be the password of the runtime database user.
   K. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.
L. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.

   A. For `source.domain.DbType`, type of the database you are currently configured to use. The value for `source.domain(DbType)` is Derby by default.

   B. For `source.domain.DbName`, type the name of the database domain you are currently using.

   C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.

   D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.

   E. For `source.domain.DbUrl`, type the url currently used to access your database.

   F. For `source.domain.DbUser`, type the name of the user accessing this database.

   G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.

   A. For `db2.DbDriver`, type the name of the JDBC driver class.

   B. For `db2.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.

   C. For `db2.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.

   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Assigning custom table spaces  
**Next topic:** Configuring JCR collation support
Configuring JCR collation support

View the steps to set up JCR collation to work with your IBM® DB2 Universal Database™ Enterprise Server Edition database. JCR collation is recommended when the language locales of your users do not natively collate correctly in the DB2 database and when language locale correct ordering is important.

- **Prerequisites**
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties

1. **Stop the WebSphere Portal server:**
   ```
   stopServer.bat WebSphere_Portal -username admin_userid -password admin_password
   ```

2. **If using a remote DB2 server**, copy the following files from the WebSphere Portal server to a temporary directory on the remote DB2 server:
   ```
   PortalServer_root/jcr/prereq.jcr/config/collation.jar
   PortalServer_root/jcr/prereq.jcr/config/registerCollationUDFTemplate.sql
   ```

3. **Set up collation on the database where the JCR domain is located.** Log in to the database machine with a userid that is authorized and configured to use the appropriate DB2 instance. For example, a common userid is `db2inst1`.
   A. Change to the directory `db2home/function`.
   B. Execute the command:
      ```
      Remote DB2: db2home/java/jdk/bin/jar -xvf temporary location/collation.jar
      Local DB2: db2home/java/jdk/bin/jar -xvf PortalServer_root/jcr/prereq.jcr/config/collation.jar
      ```
   C. Change to the directory `wp_profile_root\PortalServer\jcr\config`. If using a remote DB2, change to the temporary directory where you copied the files in a previous step.
   D. Open the file `registerCollationUDFTemplate.sql` and change all `SCHEMA` references to the JCR schema; for example, `JCR`. The value set for `SCHEMA` should match the value set for the `jcr.DbSchema` property.
   E. Connect to the JCR database by running `db2 connect to <jcrdb> user <userid> using <password>`.
   F. Execute the script by running the command:
      ```
      Remote DB2: db2 -tvf temporary location/registerCollationUDFTemplate.sql
      Local DB2: db2 -tvf wp_profile_root\PortalServer\jcr\config/registerCollationUDFTemplate.sql
      ```
   G. Disconnect from the JCR database.
   H. Restart the DB2 instance.

4. **Verify that the UDF is registered properly.**
   A. Log in as the `db2instanceID`. Open a DB2 terminal window, and type `db2`. From the command line, type the command `connect to <jcrdb> user <userid> using <password>`. You must connect to the JCR database using the userid and password of the WebSphere Portal JCR data source.
   B. Execute the following command in the previous substep. If the command completes successfully, the UDF is registered correctly as follows: `values schema.sortkeyj('abc','en')`, where `schema` is the schema used in the previous substep.

5. **Edit the `icm.properties` file**, located in `wp_profile_root\PortalServer\jcr\lib\com\ibm\icm` directory. Add the following section to the end of the file:
   ```
   # Enable/Disable collation support for all DB2 platforms
   ```
# Disabled by default

jcr.query.collation.db2.enabled = true

# Database specific collation mappings

# These mappings apply map a Java locale name into a collation name
# supported by the underlying database.
# Example mappings for DB2 platform

# English
jcr.query.collation.en = en

# Swedish
jcr.query.collation.sv = sv

jcr.query.collation.zh = zh
jcr.query.collation.de = de
jcr.query.collation.da = da
jcr.query.collation.hu = hu
jcr.query.collation.jp = jp

6. Enter the following command to start the WebSphere Portal server:

```
startServer.bat WebSphere_Portal
```
Configuring WebSphere Portal to use DB2

View information on manually transferring data to the DB2 database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

- Ensure that the following prerequisites are met:
  - Supported database software is installed.
  - Databases and users are set up.

**Prerequisites**
- Installing DB2
- Create users
- Creating remote databases
- Modifying database properties

**Tips:**

- To run these tasks as a non-root user, you must first run the task chown -R non-root_userWebSphereDir.
- If you are transferring from Oracle, the open_cursors setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.
- Be sure that DB2 is started by checking the service. If attempts to restart result in a logon failure message, then go to the DB2 properties and reenter the password.

**Steps for transferring data to another supported database**

1. If you are running a type 2 connection, before transferring data edit the db2cli.ini file. Failure to follow these steps will cause the database transfer to hang at the task action-process-constraints.
   
   A. Locate the file C:\Program Files\IBM\SQLLIB\db2cli.ini.
   
   B. Add the following to the end of the file. Leave an empty line after ReturnAliases=0.[COMMON]

   ```
   DYNAMIC=1
   ReturnAliases=0
   ```

2. Open a command prompt and change to the directory wp_profile_root\ConfigEngine.

3. Enter the following commands to validate configuration properties. ConfigEngine.bat validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password

   ```
   ConfigEngine.bat validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```

4. From the same command prompt as the previous steps, change to the directory wp_profile_root\bin.
5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td><code>stopServer.bat server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td><code>stopServer.bat WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>

6. Transfer the database. **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

A. Change to the directory `wp_profile_root\ConfigEngine`.

B. Enter the following command:

```bash
ConfigEngine.bat database-transfer -DWasPassword=password
```

**Note:**
- To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

```
ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
```
- If you have been storing data in IBM® Derby for a long time, database transfer could fail with OutOfMemory exceptions. If database transfer fails, add the following property to the command in this step:

```
ConfigEngine.bat database-transfer -DDbtJavaMaxMemory=1536M -DWasPassword=password
```

C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

7. After transferring the database tables, perform a reorg check to improve performance. Perform this step for each database alias in the property file.

A. Connect to a database with the following command:

```
db2 connect to database_alias user db2admin_userid using password
```

**Note:** Additional options might be required if additional security has been installed. Refer to DB2 Universal Database commands by example for links to the command reference.

B. After it is connected, run the following command from the DB2 prompt:

```
reorgchk update statistics on table all > xyz.out
```

C. Look in the reorg column for entries marked with a * (star or asterisk) in the file `xyz.out`. For each line with a *, note the `tablename` and run the following command for each `tablename`:

```
db2 terminate
db2rbind database_name -l db2rbind.out -u db2_admin -p password
```

D. The output file `db2rbind.out` is only created when there is an error for the `db2rbind` command.

8. Change to the directory `wp_profile_root\bin`.

9. Enter the following command to start the WebSphere Portal server:

```
startServer.bat WebSphere_Portal
```

**Parent topic:** Configuring WebSphere Portal to use DB2  
**Previous topic:** Configuring JCR collation support  
**Next topic:** Configuring DB2 for large file handling in Web Content Management

**Related Information**
Configuring DB2 for large file handling in Web Content Management

If you are using Web Content Management, you must update the database configuration to support large files. Do this by setting the `fullyMaterializeLobData` property in the WebSphere Application Server administrative console.

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configuring WebSphere Portal to use DB2

Note: You only need to perform these steps if you are using Web Content Management.

1. Log into the WebSphere Application Server administrative console.
2. Click **Resources** > **JDBC** > **Data sources**.
3. Select all scopes (the default setting) or select a specific cell, node, or node/server. Select the scope that corresponds to your instance of WebSphere Portal. The view refreshes.
4. Select the name of the data source that is defined in `wkplc_comp.properties` for the JCR database domain. The default data source is `wpdbDS`.
5. Click **Custom properties**.
6. Ensure that the `fullyMaterializeLobData` property is set to `false`.

Parent topic: Configuring WebSphere Portal to use DB2
Previous topic: Configuring WebSphere Portal to use DB2
Next topic: Changing driver types
Changing driver types

WebSphere Portal requires either JDBC Type 2 or Type 4 drivers. View the steps to switch from one driver type to the other.

Before you begin, ensure that the following conditions are met:
- The WebSphere Portal database has been successfully transferred to DB2 using the `database-transfer` configuration task.
- The files `wkplc_comp.properties` and `wkplc_dbtype.properties` have been modified to set the correct values for the DB2 drivers that you are switching to: In the file `wkplc_comp.properties` set each `<Domains>.DbUrl` property using the following formats:

  ```
  # db2 (type 2):        { jdbc:db2:wpsdb } 
  # db2 (type 4):        { jdbc:db2://<YourDatabaseServer>:50000/wpsdb:returnAlias=0; } 
  ```

  In the file `wkplc_dbtype.properties` set the `db2.DbLibrary` property using the following format: For DB2 Type 2 driver use `<SQLLIB>/java/db2java.zip` 

  For DB2 Type 4 driver use `<SQLLIB>/java/db2jcc.jar;<SQLLIB>/java/db2jcc_license_cu.jar`

  In the file `wkplc_dbtype.properties` set the `db2.DbDriver` property using the following format: For DB2 Type 2 driver use `COM.ibm.db2.jdbc.app.DB2Driver`

  For DB2 Type 4 driver use `com.ibm.db2.jcc.DB2Driver`

- Prerequisites
  - Installing DB2
  - Create users
  - Creating remote databases
  - Modifying database properties
  - Configuring WebSphere Portal to use DB2
  - Configuring DB2 for large file handling in Web Content Management

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`

2. Enter the following commands to validate configuration properties. `ConfigEngine.bat validate-database-driver` 

   ```
   DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password 
   ```

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.

4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WebSphere Application Server</strong></td>
<td>stopServer.bat server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td><strong>WebSphere Portal</strong></td>
<td>stopServer.bat WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

5. Change to the directory `wp_profile_root\ConfigEngine`.

6. To change from one supported driver to the other, run the following task to connect the database, including only the domains that require the switch: `ConfigEngine.bat connect-database`
7. Change to the directory `wp_profile_root\bin`.
8. Enter the following command to start the WebSphere Portal server:
   `startServer.bat WebSphere_Portal`
Configuring WebSphere Portal to use DB2 for z/OS

View information on installing and setting up DB2 for z/OS to work with WebSphere Portal.

   View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

2. Creating users
   Complete this procedure to set up users for IBM DB2 Universal Database™ for z/OS® to work with IBM WebSphere Portal.

3. Creating remote databases
   A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

4. Optional: Creating the Java Content Repository database
   View information on setting up your Java Content Repository database to work with WebSphere Portal.

5. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

6. Configuring WebSphere Portal to use DB2 for z/OS
   View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing DB2 for z/OS

View information on how to install DB2 for z/OS for use with IBM® WebSphere® Portal.

The following prerequisites must exist separately from the WebSphere Portal installation:

- If you are using the DB2 Legacy Type 2 JDBC driver, configure your DB2 Connect client with the following commands:
  - `db2 update dbm cfg using tp_mon_name WAS`
  - `db2 update dbm cfg using spm_name hostname`, where `hostname` is the host name for the machine where the DB2 Connect client is installed (same as portal machine).

- If you are using the DB2 Legacy Type 2 JDBC driver, enable extended shared memory usage with the following commands:
  - `export EXTSHM=ON`
  - `db2set DB2ENVLIST=EXTSHM`
  - `db2start`

To make the change permanent, you must add the environment variable by adding the following to the `profile.env` file:

```
DB2ENVLIST='EXTSHM'
```

in `/home/db2inst/sqllib/userprofile`

add: `export EXTSHM=ON`

**Note:** The shell must be reopened before restarting DB2 for z/OS.

- Both type 2 and type 4 drivers are supported. If you are using the DB2 Legacy Type 2 JDBC driver, the DB2 Connect client must be installed on the same machine as WebSphere Portal to connect to the remote database.
- The DB2 subsystem must be on a supported z/OS platform.
- Update the BP8K0 catalog bufferpool to 35,000 buffers before performing database transfer. You should change this value based on your environment. The SYSIBM.SYSDATABASE table resides in this bufferpool and is used extensively by DB2 for z/OS during database transfer.

To use DB2 for z/OS as the database software for WebSphere Portal, you must have DB2 for z/OS installed on your z/OS system. Refer to the DB2 for z/OS product documentation for instructions. Refer to the Planning for DB2 for z/OS topic for additional considerations for configuring DB2 for z/OS as the WebSphere Portal database.

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS

**Next topic:** Creating users
Creating users

Complete this procedure to set up users for IBM® DB2 Universal Database™ for z/OS® to work with IBM WebSphere® Portal.

Before you begin: You should have completed Installing DB2 for z/OS.

- Prerequisites
  - Installing DB2 for z/OS

- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.
- If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, you must create a unique database user for each WebSphere Portal instance. By default all database table names include the name of the database user used to access the data. Therefore, to prevent table name conflicts, you must create a unique database user for each WebSphere Portal instance on the shared DB2 for z/OS subsystem.
- Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

Use the following steps to grant access permissions to the database users. Repeat these steps for each WebSphere Portal instance you are setting up.

1. Create all database user IDs in the security product you are using on z/OS. For jcrschema, the database schema name for IBM Java Content Repository data, create a group and connect it to the database user ID for Java Content Repository data, jcr. The following sample shows the RACF definition of such a user ID and group, where jcr is the database user ID for Java Content Repository data, yourDefaultUserGroup is your default RACF group for database user IDs, jcrschema is the database schema name for Java Content Repository data, and yourDefaultGroup is your default RACF group for groups. If you have some other security product such as Top Secret or ACF2 instead of RACF, translate the sample RACF definition into the appropriate syntax before running the job.

   ADDUSER jcr DFLTGRP(yourDefaultUserGroup) NAME('WAS DB2 ACCESS USER')
   PW USER(jcr) NOINTERVAL
   ALU jcr PASSWORD(********) NOEXPIRED
   ADDGROUP jcrschema SUPGROUP(yourDefaultGroup)
   CONNECT jcr GROUP(jcrschema)

2. Run the following SQL statements using a tool like SPUFI while logged on to the DB2 subsystem to grant appropriate rights on the newly created databases. If you are configuring multiple WebSphere Portal instances to use a single DB2 for z/OS subsystem, be sure to use the database user associated with the database user ID for Java Content Repository data, jcr. The following sample shows the SQL statements for granting access rights.

   *Note:* Make sure your vmmdb user follows these same standards.

where:
2024
- releasenameonzos, communitynameonzos, customizationnameonzos, and releasusr, communityusr, customizationusr represent the databases and database users, respectively, of the WebSphere Portal instance you are setting up. (These users must be created on the host system.)
- jcrdbnameonzos and jcr are the database and database user, respectively, for Content Repository data.
- fdbkdbnameonzos and feedback are the database and database user, respectively, for Feedback data.
- lmdbnameonzos and lmdbusr are the database and database user, respectively, for Likeminds data.
- jcrschema is the database schema name for Content Repository data.

3. Grant the necessary access rights to all users who might require them. Depending on the architecture that you choose, these users might include Java Content Repository and Feedback users.

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Installing DB2 for z/OS
Next topic: Creating remote databases
Creating remote databases

A remote database resides on a different machine than WebSphere Portal. You must manually create the required databases before configuring WebSphere Portal to work with DB2 for z/OS.

Before you begin, complete the following prerequisites:

- These instructions assume that you will use a local IBM® DB2 Universal Database™ Enterprise Server Edition Connect to connect to a remote IBM DB2 Universal Database for z/OS® server, and that IBM WebSphere® Application Server, WebSphere Portal, and DB2 Connect will be installed on the same machine.
- To run SQL statements, you can use a tool like SPUFI. The specified statements include CREATE STOGROUP, CREATE DATABASE and CREATE TABLESPACE. For CREATE STOGROUP you have to replace the `icmvolumes` and `icmvcat` variables with volume serial numbers and a catalog name for your environment. For CREATE TABLESPACE you can specify a specific BUFFERPOOL. Refer to the DB2 for z/OS SQL Reference for a description of these options.
- Ensure that a TEMP database is created for your subsystem. You can use the following statements to create a TEMP database:

```
CREATE DATABASE db_name AS TEMP;
CREATE TABLESPACE ts_name IN db_name;
```

- Log on to the DB2 subsystem on the host server. DB2 system administrator rights are needed to create the databases.
- Replace variables as follows:

  - `releasenameonzos`, `communitynameonzos`, and `customizationnameonzos` are the WebSphere Portal databases for WebSphere Portal and Member Manager data.
  - `fdbkdbnameonzos` and `fdbkdbts` are the database and table space, respectively, for Feedback data.
  - `lmdbnameonzos` and `lmdbts` are the database and table space, respectively, for LikeMinds data.
- Because large objects are stored in columns that can become very large, logging changes to these columns requires a huge amount of log space. For this reason, large object (LOB) logging is disabled by default for table spaces that contain such data. With LOB logging disabled, you can recover full backups, but not incremental backups that can be used for point in time recovery. To recover point in time backups, you must enable LOB logging. For detailed instructions, see Technote 1306637, Managing LOB logging in DB2 for z/OS.

**Prerequisites**

- Installing DB2 for z/OS
- Creating users

Use the following steps to set up WebSphere Portal with a remote instance of DB2 for z/OS. Refer to Planning for DB2 for z/OS for a list of databases and table space names. If you are configuring multiple WebSphere Portal instances to use a single DB2 subsystem, be sure to use the database and table space names associated with the WebSphere Portal instance you are setting up.

1. CREATE DATABASE `releasenameonzos` CCSID UNICODE;
2. CREATE DATABASE `communitynameonzos` CCSID UNICODE;
3. CREATE DATABASE `customizationnameonzos` CCSID UNICODE;
4. Execute the steps in the topic Creating the Java Content Repository database.
5. CREATE DATABASE `fdbkdbnameonzos` CCSID UNICODE;
6. CREATE TABLESPACE `fdbkdbts` IN `fdbkdbnameonzos` USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500 LOCKSIZE ROW;
7. CREATE DATABASE `lmdbnameonzos` CCSID UNICODE;
CREATE TABLESPACE lmdbts IN lmdbnameonzos USING STOGROUP SYSDEFLT PRIQTY 5000 SECQTY 500;

Creating the Java Content Repository database

View information on setting up your Java Content Repository database to work with WebSphere Portal.

First, you need to create multiple databases for scalability. The IBM Java Content Repository database grows in size as the IBM® WebSphere® Portal server is used. To support this growth, which includes the dynamic creation of many new tables within the database, the WebSphere Portal server allows you to create multiple databases within a single IBM DB2 Universal Database™ for z/OS® subsystem. A minimum of two databases is recommended, but more can be created if necessary. A single database setup is not recommended; it will quickly become constrained. See the Performance guides on the product documentation Web site for more information.

Each database that is created must begin with a common prefix; there is no convention required for the remainder of the name. For example, to create \textit{xx} number of databases, you may choose to use the following commands:

\begin{verbatim}
CREATE DATABASE JCRDB01
CREATE DATABASE JCRDB02
...  
CREATE DATABASE JCRDBxx
\end{verbatim}

In this case, \textit{JCR} is the common prefix. You also have to select a maximum number of user-defined tables (UDT) that each database will be allowed to hold; the recommended value is 400.

- **Prerequisites**
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

A sample script of the commands that you can use to create the Java Content Repository database in your DB2 for z/OS installation is shown below. The sample demonstrates the creation of a single database. To follow the recommendation of creating at least two databases, duplicate the commands for each additional database as indicated below. Find a template of these commands in the file \texttt{PortalServer_root/installer/wconfig/config/templates/db/db2_zos/jcr_sample.sql}.

**Notes:**
- It is not necessary to duplicate every tablespace definition in every database.
- In order to run the commands shown in the sample, you must know the database name and the IDs of the MVS volumes where the Java Content Repository database tables will be stored.
- Edit the template file for your installation environment before running the commands shown in the sample:
  - Replace \texttt{jcrdbnameX} with the name of the database. Remember that each database name must begin with a common prefix.
  - Replace \texttt{stogroup} with the name of your storage group.
  - Replace \texttt{icmvolumes} with the IDs of the MVS volumes where the Java Content Repository database tables will be stored. These values are assigned by the database administrator.
  - Replace \texttt{icmvcat} with the name of the virtual catalog.
  - Replace \texttt{jcr} with the name of database user ID.
  - Replace \texttt{4kbp} with the name of your 4K bufferpool.
  - Replace \texttt{32kbp} with the name of your 32K bufferpool.
  - Replace \texttt{jcrschema} with the schema name of your Java Content Repository domain.
CREATE DATABASE jcrdbname

CREATE STOGROUP stogroup VOLUMES (icmvolumes) VCAT icmvcat

GRANT USE OF STOGROUP stogroup to jcr

CREATE DATABASE jcrdbname STOGROUP stogroup BUFFERPOOL 4kbp INDEXBP 4kbp CCSID UNICODE

Note: The following two tablespace commands must be created in every database:

CREATE TABLESPACE ICMLFQ32 IN jcrdbname USING STOGROUP stogroup PRIQTY 50000 SECQTY 10000 FREEPAGE 1 PCTFREE 5 LOCKSIZE ROW SEGSIZE 32 LOCKMAX 0 CLOSE NO BUFFERPOOL 32kbp CCSID UNICODE

Parent topic: Configuring WebSphere Portal to use DB2 for z/OS
Previous topic: Creating remote databases
Next topic: Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root
  /PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.
- When using IBM® DB2 Universal Database™ for z/OS® as a data store, WebSphere Portal requires that its indexes are not padded. Therefore, you must set the DSNZPARM parameters to RETVLCFK=NO or PADIX=NO, or both.

Prerequisites
- Installing DB2 for z/OS
- Creating users
- Creating remote databases

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each .tablespace entry in the mapping file. Assignments to .indexspace entries are ignored.
   The table space name must be qualified by the database name and prepended by the keyword IN and a space. For example: community.COMP_INST.tablespace=IN COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: ./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true
- i5/OS: ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true

**Parent topic:** Configuring WebSphere Portal to use DB2 for z/OS  
**Previous topic:** Creating the Java Content Repository database  
**Next topic:** Configuring WebSphere Portal to use DB2 for z/OS
Configuring WebSphere Portal to use DB2 for z/OS

View information on manually transferring data to the DB2 for z/OS you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to DB2 for z/OS. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:
- Supported database software is installed.
- Databases and users are set up.

- Prerequisites
  - Installing DB2 for z/OS
  - Creating users
  - Creating remote databases

Tips:
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

Steps for transferring data to another supported database

1. If you are running a type 2 connection, before transferring data edit the `db2cli.ini` file. Failure to follow these steps will cause the database transfer to hang at the task `action-process-constraints`.
   A. Locate the file `C:\Program Files\IBM\SQLLIB\db2cli.ini`.
   B. Add the following to the end of the file. Leave an empty line after `ReturnAliases=0`. [COMMON]
      ```
      DYNAMIC=1
      ReturnAliases=0
      ```

2. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`.

3. Enter the following commands to validate configuration properties.
   ```
   ConfigEngine.bat validate-database-driver -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ConfigEngine.bat validate-database-connection -DTransferDomainList=release,customization,community,jcr,feedback,likeminds -DWasPassword=password
   ```

4. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.

5. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>stopServer.bat server1 -username admin_userid -password admin_password</code></td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td><code>stopServer.bat WebSphere_Portal -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>
6. **Transfer the database:**

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root\ConfigEngine`.

   B. Enter the following command:
   ```cmd
   ConfigEngine.bat database-transfer -DWasPassword=password
   ```

   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:
   ```cmd
   ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

    If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

7. From the command line processor, reset the check pending status on the WebSphere Portal table spaces listed here.

   **CHECK DATA** is a DB2 batch utility that is invoked through JCL or through the DB2 utility panels. Type the following utility commands to check pending status:
   ```bash
   check data tablespace releasenameonzos.TS280A
   check data tablespace releasenameonzos.TS300A
   check data tablespace releasenameonzos.TS2110A
   check data tablespace releasenameonzos.TS830A
   check data tablespace communitynameonzos.TS8000B
   check data tablespace communitynameonzos.TS8011B
   check data tablespace communitynameonzos.TS280B
   check data tablespace customizationnameonzos.TS2110C
   check data tablespace jcrdbnameonzos.ICMSFQ04
   check data tablespace jcrdbnameonzos.TS2110D
   ```

   where `releasenameonzos`, `communitynameonzos`, and `customizationnameonzos` are the names of your WebSphere Portal databases, and `jcrdbnameonzos` is the name of your JCR database. Refer to the *Utility Guide and Reference for DB2 for z/OS* for additional details.

8. Run the `RUNSTATS` utility as shown in the following example:
   ```bash
   LISTDEF JCRDBZOS INCLUDE TABLESPACE JCRDBZOS.*  BASE
   RUNSTATS TABLESPACE LIST JCRDBZOS INDEX(ALL) KEYCARD TABLE(ALL)
   LISTDEF JCRDB01 INCLUDE TABLESPACE JCRDB01.*  BASE
   RUNSTATS TABLESPACE LIST JCRDB01 INDEX(ALL) KEYCARD TABLE(ALL)
   ...
   ```

9. Start the WebSphere Application Server.

10. Verify that the WebSphere Portal application server is running by opening the following URL in a browser:

    ```http://hostname.companyname.com:port_number/wps/portal```

    where `hostname.companyname.com` is the fully qualified host name of the machine where WebSphere Portal is running and `port_number` is the transport port that is created by WebSphere Application Server.

If you have performed database transfer in a clustered environment, you must explicitly copy the `wp_profile_root\PortalServer\jcr\lib\com\ibm\icm\icm.properties` file from the primary node on which the `database-transfer` task was processed to all secondary nodes. This ensures that the secondary nodes have the new JCR database values specified in the `icm.properties` file.

1. Stop the portal server on the secondary node.

2. Copy the `wp_profile_root\PortalServer\jcr\lib\com\ibm\icm\icm.properties` file from the primary node and replace the `icm.properties` file on the secondary node with the new file from the primary node.

3. Start the portal server on the secondary node.
Configuring WebSphere Portal to use Oracle

View information on installing and setting up Oracle to work with WebSphere Portal.

   View information on how to install Oracle for use with WebSphere Portal.

2. Creating users
   View the steps to set up users for Oracle to work with WebSphere Portal.

3. Creating databases
   View some important considerations before setting up Oracle databases to work with WebSphere Portal.

4. Modifying database properties
   Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

5. Setting up databases
   This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces.

6. Creating JCR table spaces
   This topic provides manual instructions for creating JCR table spaces for Oracle.

7. Optional: Assigning custom table spaces
   The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

8. Configuring WebSphere Portal to use Oracle
   View information on manually transferring data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Parent topic: Configure WebSphere Portal to use a remote database
Installing Oracle

View information on how to install Oracle for use with WebSphere Portal.

You can use Oracle as the database software. You must install Oracle separately and before performing a database transfer.

Refer to Oracle product documentation for installation instructions.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Next topic:** Creating users
Creating users

View the steps to set up users for Oracle to work with WebSphere Portal.

Before you begin:

- You should have installed Oracle.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

**Prerequisites**

- Installing Oracle

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Start the Oracle SQL command line processor 'SQL*Plus' by entering `sqlplus /nolog` on the operating system command prompt
2. Log in to the Oracle database by executing command `connect user/password@database name`. For example: `system/manager@wpsdb` will log the administrative user system with a password of manager into the wpsdb database.
3. Create the WebSphere Portal user `dbdomain.DbUser`, where `dbdomain` is replaced by release, community, or customization.
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following commands in the SQL*Plus tool, where `user_tablespace` is the default tablespace that is identified by the database administrator to store user objects and `temp_tablespace` is identified to store temporary objects. All names must be in lower case. `SQL> create user releaseusr identified by password` `default tablespace user_tablespace` `temporary tablespace temp_tablespace;` `GRANT UNLIMITED TABLESPACE TO releaseusr;` `SQL> create user communityusr identified by password` `default tablespace user_tablespace temporary tablespace temp_tablespace;` `GRANT UNLIMITED TABLESPACE TO communityusr;` `SQL> create user customizationusr identified by password` `default tablespace user_tablespace` `temporary tablespace temp_tablespace;` `GRANT UNLIMITED TABLESPACE TO customizationusr;` `SQL> create user jcr identified by password` `default tablespace user_tablespace` `temporary tablespace temp_tablespace;` `GRANT UNLIMITED TABLESPACE TO jcr` 4. Connect to the Feedback database:
   A. Enter the following command: `SQL> connect`
B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database. For example, `system/manager@fdbkdb` will log the administrative user system with a password of manager into the `fdbkdb` database.

C. Create the Feedback user:

```
SQL> create user feedback identified by password
    default tablespace user_tablespace
    temporary tablespace temp_tablespace;
```

GRANT UNLIMITED TABLESPACE TO `feedback`

D. Log out of the command line tool using the command `SQL> exit`.

5. Connect to the LikeMinds database:

A. Enter the following command:

```
SQL> connect
```

B. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database.

   For example, `system/manager@lmdb` will log the administrative user system with a password of manager into the `lmdb` database.

C. Create the LikeMinds user:

```
SQL> create user lmdbusr identified by password
    default tablespace user_tablespace
    temporary tablespace temp_tablespace;
```

GRANT UNLIMITED TABLESPACE TO `lmdbusr`

D. Log out of the command line tool using the command `SQL> exit`.

6. Perform the following steps to verify that you can connect to the database with the user ID and password that you just created:

A. Enter the `SQL> connect` command to connect to the content database.

B. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@jcrdb` will log the administrative user system with a password of manager into the Oracle database.

---

Parent topic: Configuring WebSphere Portal to use Oracle

Previous topic: Installing Oracle

Next topic: Creating databases
Creating databases

View some important considerations before setting up Oracle databases to work with WebSphere Portal.

For information about creating databases, refer to the Oracle product documentation. For information on the recommended database architecture and the databases you will need to create, see the Planning for Oracle topic. Be sure that all databases to be used with WebSphere Portal are created as UNICODE character set databases.

If you are using remote Oracle 9 or 10 databases, you must also copy the ojdbc14.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM® WebSphere® Application Server Version 7.0, you must also copy the ojdbc6.jar file from the remote Oracle server to the WebSphere Portal machine. If you are using remote Oracle 11 database with IBM WebSphere Application Server Version 6.1, you must also copy the ojdbc5.jar file from the remote Oracle server to the WebSphere Portal machine. The typical location is the oracle_home/sqldeveloper/jdbc/lib directory. Record the copy location on your local machine for future reference.

When creating Oracle databases for use with WebSphere Portal, you should consider the following information:

- The Oracle databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle server will be remote or local to the WebSphere Portal installation.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle database in order for WebSphere Portal to communicate with the Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes:

  - `db_block_size` = 8192 bytes
  - `db_cache_size` = 307,200 bytes
  - `db_files` = 1024 files
  - `log_buffer` = 65536 bytes
  - `open_cursors` = 1500 cursors
  - `pga_aggregate_target` = 204,800 bytes
  - `pre_page_sga` = true
  - `processes` = 300 processes
  - `shared_pool_size` = 204,800 bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the Java Content Repository schema.

- Raise the number of parallel servers as appropriate. For example, if you have more than 875 parallel servers, you should set the `parallel_max_servers` to 1200.

- The Oracle parameter CURSOR_SHARING allows similar SQL Statements to be shared when possible, which prevents parsing and establishing a new execution plan. The execution plan is used by Oracle to gather the data needed to satisfy a request. There are two options for CURSOR_SHARING, which are as follows:
  - **FORCE**
    - When you select this option, Oracle uses the same execution plan for all SQLs that are similar in value even if the values are different. When you use this option, the execution plan may not provide optimum performance. For example, similar SQLs with different values may behave differently when executed running the same plan.
  - **EXACT**
When you select this option, Oracle only shares the same execution plan for SQLs that are identical and use the same values. This option removes the risk of a SQL statement being executed when optimum performance conditions do not exist.

WebSphere Portal supports both options. Regardless of the option selected, portlet applications should not be affected. Contact your database administrator for further assistance on these options.

**Prerequisites**

- Installing Oracle
- Creating users

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Creating users

**Next topic:** Modifying database properties
Modifying database properties
Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

Tip: For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

Working with properties files:
- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as release.DbName, jcr.DbName, feedback.DbName, and likeminds.DbName. For example:
  - release.DbName=release
  - jcr.DbName=jcrdb
  - feedback.DbName=fdbkdb
  - likeminds.DbName=lmdb
  - community.DbName=commdb
  - customization.DbName=custom
- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.
- Depending on which database domain has to be configured, replace dbdomain with:
  - release
  - customization
  - community
  - jcr
  - feedback
  - likeminds
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - dbdomainDbType
- `dbdomain.DbName`
- `dbdomain.DbUrl`
- `dbdomain.DbSchema`

If you use the same values for all four properties across the release, customization, community, and JCR domains, the database-transfer task fails because of ambiguous database object names. If `DbUser`, `DbUrl`, and `DbPassword` are not the same across domains, the value for `DataSourceName` must differ from the `DataSourceName` of the other domains. In other words, this value must be unique for the database domain.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

1. Locate the following files and create a backup copy of each before changing any values:
   - `wp_profile_root/ConfigEngine/properties/wkplc.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_comp.properties`
   - `wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties`

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In `wkplc_comp.properties`, most properties are repeated for each domain.

2. Use a text editor to open the properties file `wkplc_comp.properties` and modify the values to correspond to your environment.
   
   A. For `dbdomainDbType`, type `oracle`.
   
   B. For `dbdomain.DbName`, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the `dbdomain.DbUrl` property.
   
   C. For `dbdomain.DbSchema`, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The `dbdomain.DbName` should be the same value used for the `dbdomain.DbSchema`.

       **Restriction:** The value for `dbdomain(DbSchema)` must equal the value for `dbdomain(DbUser)`.

   D. For `dbdomain.DataSourceName`, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
   - `releaseDS`
   - `communityDS`
   - `customizationDS`
   - `jcrDS`
   - `lmdbDS`
   - `feedback`

   E. For `dbdomain.DbUrl`, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:**
   - The database element of this value should match the value of `DbName`.
   - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
     
     ```
     jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME.
     ```
     
     When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

   F. For `dbdomain.DbUser`, type the user ID for the database administrator. **Restriction:** The value for `dbdomain(DbUser)` must equal the value for `dbdomain(DbSchema)`.
G. For `dbdomain.DbPassword`, type the password for the database administrator.
H. For `dbdomain.DBA.DbUser`, type the database administrator user ID for privileged access operations during creation of the database.
I. For `dbdomain.DBA.DbPassword`, type the database administrator password for privileged access operations during creation of the database.
J. For `dbdomain.DbHome`, type the root location for the database. **Note:** This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in `wkplc_comp.properties`. **Important:** The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.
A. For `source.domain.DbType`, type of the database you are currently configured to use. The value for `source.domain.DbType` is Derby by default.
B. For `source.domain.DbName`, type the name of the database domain you are currently using.
C. For `source.domain.DbSchema`, type current schema identifier for objects within the database for this domain.
D. For `source.domain.DataSourceName`, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For `source.domain.DbUrl`, type the url currently used to access your database.
F. For `source.domain.DbUser`, type the name of the user accessing this database.
G. For `source.domain.DbPassword`, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file `wkplc_dbtype.properties`.
   A. For `oracle.DbDriver`, type the name of the class that SqlProcessor uses to import SQL files.
   B. For `oracle.DbLibrary`, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
   C. For `oracle.JdbcProviderName`, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file `wkplc.properties`.
   A. For `WasPassword`, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

**Parent topic:** Configuring WebSphere Portal to use Oracle

**Previous topic:** Creating databases

**Next topic:** Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces.

- **Prerequisites**
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties

As an alternative to automatically setting up the database, you can manually set up your database by referring to the link in the related tasks section of this topic.

1. On the database server, make sure that the folder `db_1` contains the subfolders `your_oracle_instance/data` and `your_oracle_instance/index`. If this folder hierarchy does not exist, create it manually before you run the `setup-database` task. The `setup-database` task requires these folders to create database users. If these folders do not exist, the `setup-database` task will fail.

2. Change to the directory `wp_profile_root/ConfigEngine`

3. To create the database users, type the following command:

   ```
   ConfigEngine.bat setup-database -DWasPassword=password
   ```

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires `db_owner` permission for the database user. The script that creates users is invoked by the configuration task `setup-database` and is located in the installation directory of WebSphere Portal:

   `<WP_root>/base/wp.db.impl/config/templates/setupdb/sqlserver2005\<database domain>\createUsers.sql`.

Parent topic: Configuring WebSphere Portal to use Oracle

Previous topic: Modifying database properties

Next topic: Creating JCR table spaces

Related tasks
Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.
2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.
   - Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

```sql
create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
create tablespace ICMLNF32 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMV04_01.dbf' size 25M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMSFQ04_01.dbf' size 150M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
create tablespace ICMLNDFX datafile '&dbpath./&jcrdb./index/&jcrdb._ICMLNDFX_01.dbf' size 10M reuse autoextend on next 10M maxsize UNLIMITED extent management local autoallocate;
```

A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.
B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.
C. Refer to the Oracle command reference for more information about using the `create tablespace` command.
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:

- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

- Prerequisites
  - Installing Oracle
  - Creating users
  - Creating databases
  - Modifying database properties
  - Setting up databases
  - Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file wp_profile_root/PortalServer/config/tablespaces/dbdomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - dbdomain.table_name.tablespace
   - dbdomain.table_name.index_name.indexspace
   
   For the file name and each table space and index space property pair, dbdomain can be any one of the following values:
   - release
   - community
   - customization
   - jcr
   - feedback
   - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   
   Repeat this step for each domain that you are transferring.
4. Save and close dbdomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- **UNIX**: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- **i5/OS**: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Parent topic:** Configuring WebSphere Portal to use Oracle  
**Previous topic:** Creating JCR table spaces  
**Next topic:** Configuring WebSphere Portal to use Oracle
Configuring WebSphere Portal to use Oracle

View information on manually transferring data to the Oracle database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:
Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**Prerequisites**
- Installing Oracle
- Creating users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

**Tips:**
- If you are transferring from Oracle, the `open_cursors` setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`.
2. Enter the following commands to validate configuration properties. `ConfigEngine.bat validate-database-driver` -
   `DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password`
3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.
4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td><code>stopServer.bat server1 -username admin_userid -password admin_password</code></td>
</tr>
</tbody>
</table>
5. Transfer the database. **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root\ConfigEngine`.

   B. Enter the following command:

   ```
   ConfigEngine.bat database-transfer -DWasPassword=password
   ```

   **Note:** To select specific database domains to transfer, modify the `-DTransferDomainList` specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

   ```
   ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password
   ```

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

   ```sql
   SQL> execute dbms_stats.gather_schema_stats(ownname=>'jcr', cascade=>TRUE);
   ```

7. Change to the directory `wp_profile_root\bin`.

8. Enter the following command to start the WebSphere Portal server:

   ```
   startServer.bat WebSphere_Portal -username admin_userid -password admin_password
   ```

**Parent topic:** Configure WebSphere Portal to use a remote database
Installing Oracle RAC

View information on how to install Oracle RAC for use with WebSphere Portal.

Before you begin:
- You should have completed reviewing the Planning for Oracle RAC section.
- Ensure the Oracle CRS (Cluster Ready Service) and Oracle RAC databases have been installed and configured on the primary and secondary nodes.
- Run the following commands on both RAC nodes to start global services daemon (GSD), oracle listeners, and agents.
  - $ gsdctl start
  - $ lsnrctl start
  - $ agentctl start

You can use Oracle RAC as the database software for WebSphere Portal. You must install Oracle RAC separately and before performing WebSphere Portal database transfer.

Refer to Oracle product documentation for installation instructions.

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Next topic: Create users
Create users

View the steps to set up users for Oracle RAC to work with WebSphere Portal.

Before you begin:

- You should have completed installing Oracle RAC.
- If WebSphere Portal Version 6.1.5 and an earlier version of WebSphere Portal coexist, the database user IDs for WebSphere Portal Version 6.1.5 must be different than earlier versions to avoid conflicts during installation.

- Prerequisites
  - Installing Oracle RAC

Ensure that you create users and grant the appropriate privileges in Oracle before configuring WebSphere Portal to work with Oracle.

Take care to create users in an environment that has the same settings as the actual runtime environment. For example, avoid creating a user in an English environment if you plan to use that user in a Turkish environment.

1. Create the users in the WebSphere Portal databases
   A. Log in to the database in which you want to create the new users.
   B. Create the users that you need in the appropriate databases by entering the following command in the SQL*Plus tool, where user_tablespace is the default tablespace that is identified by the database administrator to store user objects and temp_tablespace is identified to store temporary objects:

   \[
   \text{SQL} > \text{create user username identified by password default tablespace user_tablespace temporary tablespace temp_tablespace;}
   \]

   Tip: Balance the storage of user objects among tablespaces to prevent running out of space with overuse of user_tablespace. Also consider increasing the size of user_tablespace when handling a high volume of users.

2. Log in by entering the command \$\text{sqlplus} in SQL*Plus:

3. Enter the command \texttt{user-name: username/password@dbname}, where \texttt{username} is an existing administrative user in the database. For example: system/manager@wpsdb will log the administrative user system with a password of manager into the wpsdb database.

4. Create the WebSphere Portal user \texttt{dbdomain.DbUser}, where \texttt{dbdomain} is replaced by release, community, customization, or JCR. All names must be in lower case. The following code uses the default user tablespace and the default temporary tablespace. Explicitly specify these tablespaces if you do not want to use the defaults.

   \[
   \text{SQL} > \text{create user releaseusr identified by password;}
   \text{SQL} > \text{create user communityusr identified by password;}
   \text{SQL} > \text{create user customizationusr identified by password;}
   \text{SQL} > \text{create user jcr identified by password;}
   \]

5. Connect to the content database by entering the command \texttt{SQL > connect}.

6. Enter the following, where \texttt{username} is an existing administrative user in the database \texttt{user-name: username/password@dbname}.

   For example, system/manager@jcrdb will log the administrative user system with a password of manager into the Oracle RAC database.

7. Create the Oracle RAC users by entering the following: When creating the \texttt{jcr} user, grant all necessary privileges. If you do not grant privileges, you will receive the error ICMADMIN lacks CREATE SESSION Privilege logon denied.
8. Connect to the Feedback database:
   A. Enter the following command: `SQL> connect`
   B. Enter `user-name: username/password@dbname` where `username` is an existing administrative user in the database.
      For example, `system/manager@fdbkdb` will log the administrative user `system` with a password of `manager` into the `fdbkdb` database.

9. Create the Feedback user:
   `SQL> create user feedback identified by password default tablespace users temporary tablespace temp;`

10. Connect to the LikeMinds database:
    `SQL> connect`

11. Enter `user-name: username/password@dbname`, where `username` is an existing administrative user in the database. For example, `system/manager@lmdb` will log the administrative user `system` with a password of `manager` into the `lmdb` database.

12. Create the LikeMinds user:
    `SQL> create user lmdbusr identified by password default tablespace users temporary tablespace temp;`

13. Log out of the command line tool using the command `SQL> exit`.

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Installing Oracle RAC
Next topic: Creating databases
Creating databases

View some important considerations before setting up Oracle RAC databases to work with WebSphere Portal. When creating Oracle RAC databases for use with WebSphere Portal, you should consider the following information:

- The Oracle RAC databases must be created manually before configuring WebSphere Portal.
- All databases must be created using UNICODE Database and National character sets such as UTF8, AL32UTF8, or AL16UTF16.
- It is recommended that all databases to be used with WebSphere Portal are configured in Dedicated Server Mode.
- Determine if your Oracle RAC server will be remote or local to the WebSphere Portal installation.
- If using an earlier version of Oracle RAC (9i or earlier), ensure that Oracle RAC JVM is also installed.
- After installing the database software for WebSphere Portal, you will need to set the buffer pools allocated to the Oracle RAC database in order for WebSphere Portal to communicate with the IBM Java Content Repository database. Use the following recommended values as a guide. Refer to the Oracle product documentation for information on how to set the buffer pools. Recommended initial buffer pool sizes are:

  - `db_block_size` = 8192 bytes
  - `db_cache_size` = 314,572,800 bytes
  - `db_files` = 1024 files
  - `log_buffer` = 65536 bytes
  - `open_cursors` = 1500 cursors
  - `pga_aggregate_target` = 209,715,200 bytes
  - `pre_page_sga` = true
  - `processes` = 300 processes
  - `shared_pool_size` = 209,715,200 bytes

  **Note:** If you are using IBM Java Content Repository, the `open_cursors` value may need to be increased based on the table count in the IBM Java Content Repository schema.

**Prerequisites**

- Installing Oracle RAC
- Create users
Modifying database properties

Learn how to modify the wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties files to work with your database. Modify these property files before running tasks to create databases, create users, or transfer data.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases

The wkplc.properties, wkplc_comp.properties, and wkplc_dbtype.properties are published in the IBM® WebSphere® Portal wiki. The wiki articles include examples, valid values, and descriptions to help you determine what value to provide for a given property. The documentation team and other IBM teams will update the properties to provide more examples and clarity as needed.

**Tip:** For the most up-to-date information about properties, such as examples, valid values, and more, see the following wiki articles:
- WebSphere Portal 6.1.5 wkplc.properties file reference
- WebSphere Portal 6.1.5 wkplc_comp.properties file reference
- WebSphere Portal 6.1.5 wkplc_dbtype.properties file reference

**Working with properties files:**

- The WebSphere Portal database can be used to hold information for applications such as Feedback and LikeMinds. Use similar naming conventions for property values such as `release.DbName`, `jcr.DbName`, `feedback.DbName`, and `likeminds.DbName`. For example:

  - `release.DbName=release`
  - `jcr.DbName=jcrdb`
  - `feedback.DbName=fdbkdb`
  - `likeminds.DbName=lmdb`
  - `community.DbName=commdb`
  - `customization.DbName=custdb`

- If you are using a remote database, enter the values for the remote server.
- Use a forward slash (/) instead of a backslash (\).
- There might be additional database properties other than those listed here. Only change the properties within this task and skip all other properties.
- The recommended value listed for each property represents the specific information that is required to configure WebSphere Portal to your target database.

- Depending on which database domain has to be configured, replace `dbdomain` with:
  - `release`
  - `customization`
  - `community`
  - `jcr`
  - `feedback`
  - `likeminds`
- The values for at least one of the following properties must be unique for the release, customization, community, and jcr domains:
  - `dbdomain DbType`
1. Locate the following files and create a backup copy of each before changing any values:
   - wp_profile_root/ConfigEngine/properties/wkplc.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_comp.properties
   - wp_profile_root/ConfigEngine/properties/wkplc_dbtype.properties

   Default values are listed in these files. Unless otherwise noted, all values are of type alphanumeric text string. Print out the steps below for reference before modifying the properties files. Make sure to enter the appropriate values for each instance of each property. In wkplc_comp.properties, most properties are repeated for each domain.

2. Use a text editor to open the properties file wkplc_comp.properties and modify the values to correspond to your environment.

   A. For dbdomainDbType, type oracle.

   B. For dbdomainDbName, type the name of the WebSphere Portal domain database. **Note:** This value is also the database element in the dbdomainDbUrl property.

   C. For dbdomainDbSchema, type the schema name of the database domain. **Note:** Review your target database management system documentation to define a valid schema name. Some database management systems have schema name restrictions that you need to understand. The dbdomainDbName should be the same value used for the dbdomainDbSchema.

     **Restriction:** The value for dbdomainDbSchema must equal the value for dbdomainDbUser.

   D. For dbdomainDataSourceName, type the name of the data source that WebSphere Portal uses to communicate with its databases. Do not use the following reserved words:
      - releaseDS
      - communityDS
      - customizationDS
      - jcrDS
      - lmdbDS
      - feedback

   E. For dbdomainDbUrl, type the database URL used to access the WebSphere Portal database with JDBC. The value must conform to the JDBC URL syntax specified by the database. **Note:**
      - The database element of this value should match the value of DbName.
      - For Oracle RAC only, the WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:
        jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME. When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

   F. For dbdomainDbUser, type the user ID for the database administrator. **Restriction:** The value for dbdomainDbUser must equal the value for dbdomainDbSchema.
G. For dbdomain.DbPassword, type the password for the database administrator.
H. For dbdomain.DBA.DbUser, type the database administrator user ID for privileged access operations during creation of the database.
I. For dbdomain.DBA.DbPassword, type the database administrator password for privileged access operations during creation of the database.
J. For dbdomain.DbHome, type the root location for the database. Note: This value is used to specify the location to create the tablespaces.

3. (Optional) When transferring WebSphere Portal databases from any database other than the default Derby database, update the following properties in wkplc_comp.properties. Important: The default values for the following parameters are set for the out-of-the-box Derby configuration. If you are configuring WebSphere Portal for an external database for the first time, do not modify these properties, and skip this step. If you have already configured WebSphere Portal to use a database other than the default Derby database, update the source properties for your current database settings.
A. For source.domainDbType, type of the database you are currently configured to use. The value for source.domainDbType is Derby by default.
B. For source.domainDbName, type the name of the database domain you are currently using.
C. For source.domainDbSchema, type current schema identifier for objects within the database for this domain.
D. For source.domainDataSourceName, type the name of the datasource that is currently used in your IBM WebSphere Application Server configuration.
E. For source.domainDbUrl, type the url currently used to access your database.
F. For source.domainDbUser, type the name of the user accessing this database.
G. For source.domainDbPassword, type the password of the source DbUser.

4. Save and close the file.

5. Update the following properties in the file wkplc_dbtype.properties.
   A. For oraclegetDbDriver, type the name of the class that SqlProcessor uses to import SQL files.
   B. For oraclegetDbLibrary, type the directory and name of the .zip or .jar file that contains the JDBC driver class.
   C. For oracleJdbcProviderName, type the name of the JDBC provider that WebSphere Portal uses to communicate with its databases.

6. Save and close the file.

7. Update the following property in the file wkplc.properties.
   A. For WasPassword, type the password for the WebSphere Application Server security authentication used in your environment.

8. Save and close the file.

Parent topic: Configuring WebSphere Portal to use Oracle RAC
Previous topic: Creating databases
Next topic: Setting up databases
Setting up databases

This topic provides instructions on automatically setting up your database using the ConfigEngine task to create users, grant permissions, and create Java Content Repository table spaces. As an alternative to automatically setting up the database, you can manually set up your database.

Before you begin, ensure that the following prerequisites are met:

- Supported database software is installed.
- Property files are modified.
- Database user names and passwords should not contain spaces and should comply with both the database management system software requirements and WebSphere Portal requirements for administering users and groups.

**Prerequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties

1. On the database server, make sure that the folder db_1 contains the subfolders your_oracle_instance/data and your_oracle_instance/index. If this folder hierarchy does not exist, create it manually before you run the setup-database task. The setup-database task requires these folders to create database users. If these folders do not exist, the setup-database task will fail.

2. Change to the directory wp_profile_root/ConfigEngine

3. To create the database users, type the following command:

   `ConfigEngine.bat setup-database -DWasPassword=password`

   **Note:** This task will automatically create the necessary users, permissions, and table spaces. WebSphere Portal requires db_owner permission for the database user. The script that creates users is invoked by the configuration task setup-database and is located in the installation directory of WebSphere Portal: `\<WP_root>\base\wp.db.impl\config\templates\setupdb\sqlserver2005\<database domain>\createUsers.sql`.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC

**Previous topic:** Modifying database properties

**Next topic:** Creating JCR table spaces

**Related tasks**

Manually creating users and granting privileges for Oracle
Creating JCR table spaces

This topic provides manual instructions for creating JCR table spaces for Oracle.

- **Prerequisites**
  - Installing Oracle RAC
  - Create users
  - Creating databases
  - Modifying database properties
  - Setting up databases

Refer to the following instructions for creating tablespaces:

1. In the database directory, create the data directory `data` and the index directory `index`.

2. Create tablespaces using the following commands as examples: Substitute the values of your environment for the following variables:
   - `&jcrdb` is the name of the database you created to store user data.
   - `&dbpath` is the directory where you created the database; the default path is `/oracle/oradata`.

   Ensure that the `.` is included in the variables when you substitute the values of your environment with these variables.

   **Important:** You must use the same table space names listed in the commands. The table space names cannot be customized or modified.

   ```sql
   create tablespace ICMLFQ32 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMLFQ32_01.dbf' size 300M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLNF32 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMLNF32_01.dbf' size 25M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMVFQ04 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMVFQ04_01.dbf' size 25M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMSFQ04 datafile '&dbpath./&jcrdb./data/&jcrdb._ICMSFQ04_01.dbf' size 150M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   create tablespace ICMLSNDX datafile '&dbpath./&jcrdb./index/&jcrdb._ICMLSNDX_01.dbf' size 10M reuse autoextend on
   next 10M maxsize UNLIMITED extent management local autoallocate;
   ``

A. Set the `size`, `autoextend`, and `maxsize` values according to your environment. For example, you may want to change the `maxsize` to a set value rather than `UNLIMITED`.

B. Consult your Database Administrator for specific guidance about creating tablespaces for your environment.

C. Refer to the Oracle command reference for more information about using the `create tablespace` command.

**Parent topic:** Configuring WebSphere Portal to use Oracle RAC  
**Previous topic:** Setting up databases  
**Next topic:** Assigning custom table spaces
Assigning custom table spaces

The repository of WebSphere Portal consists of many tables and indices that are created in default table spaces. When using an existing set of table spaces for the objects of the repository, specify this when executing the database transfer to the target database system.

Before you begin:
- The custom table spaces must exist prior to the execution of database transfer.
- To see which table spaces can be customized in each domain, refer to the \wp_profile_root\PortalServer\config\tablespaces\ddomain.space_mapping.properties file.
- For details on creating table spaces refer to the documentation for the database.

**Prerequisites**
- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

If custom table spaces are assigned, each must be assigned explicitly. The default table spaces can be used to contain database objects; however the name of the default table space must be specified in the corresponding mapping files. This applies to all database domains that are transferred in a single database transfer.

To configure custom table space assignments:

1. Determine the names of your custom table spaces.
2. Open the mapping file \wp_profile_root\PortalServer\config\tablespaces\ddomain.space_mapping.properties that specifies the table space and index space property pairs for each database table:
   - \ddomain.table_name.tablespace
   - \ddomain.table_name.index_name.indexspace
   For the file name and each table space and index space property pair, \ddomain\ can be any one of the following values:
     - release
     - community
     - customization
     - jcr
     - feedback
     - likeminds
3. Assign a table space to each entry in the mapping file. The table space name must be prepended by the keyword TABLESPACE and a space. For example: \community.COMP_INST.tablespace=TABLESPACE COMM8KSPACE
   Repeat this step for each domain that you are transferring.
4. Save and close \ddomain.space_mapping.properties.
5. From a command prompt, specify the option -DuseCustomTablespaceMapping=true when starting the database transfer. For example,
   - Windows: ConfigEngine.bat database-transfer -DuseCustomTablespaceMapping=true
- UNIX: `./ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`
- i5/OS: `ConfigEngine.sh database-transfer -DuseCustomTablespaceMapping=true`

**Previous topic:** Creating JCR table spaces

**Next topic:** Configure WebSphere Portal to use Oracle RAC
Configure WebSphere Portal to use Oracle RAC

View information on manually transferring data to the Oracle RAC database you have installed and set up. Follow these steps to transfer WebSphere Portal, and Java Content Repository databases to Oracle. As an alternative to the manual database transfer procedure described here, you can use the configuration wizard to complete the database transfer task.

Before you begin:

Ensure that the following prerequisites are met:

- Supported database software is installed.
- Databases and users are set up.
- Property files are modified.

**Prerequisites**

- Installing Oracle RAC
- Create users
- Creating databases
- Modifying database properties
- Setting up databases
- Creating JCR table spaces

**Tips:**

- If you are transferring from Oracle, the **open_cursors** setting should be set to 1500 by default. If you are using Java Content Repository, this value might need to be increased based on the table count in the Java Content Repository schema.

- The WebSphere Portal server must explicitly connect to one RAC node during database transfer. You need to specify the information of one Oracle RAC node as if it is the only database server. For example, the Oracle database URL should look like the following:

```
jdbc:oracle:thin:@PRIMARY_NODE_HOSTNAME:1521:PRIMARY_NODE_INSTANCENAME
```

When database transfer is completed, the WebSphere Portal server will be configured to use this single database server.

- Manually specify an RAC datasource URL in the WebSphere Application Server console. The URL should look like the following:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521)) (ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521))) (CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICE_NAME))
```

- When doing a single database, single user, and multi schema database transfer, there can be only one user for each domain (release, community, customization, JCR, Feedback, and LikeMinds), and the schema for each database must be different. The user must be a superuser or DBA and must have authority over all other schemas for the transfer to work.

**Steps for transferring data to another supported database**

1. Open a command prompt and change to the directory `wp_profile_root\ConfigEngine`.
2. Enter the following commands to validate configuration properties.

   ConfigEngine.bat validate-database-driver -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password

   ConfigEngine.bat validate-database-connection -DTransferDomainList=release,customization,community, jcr,feedback,likeminds -DWasPassword=password

3. From the same command prompt as the previous steps, change to the directory `wp_profile_root\bin`.

4. Stop both WebSphere Application Server and the WebSphere Portal server:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebSphere Application Server</td>
<td>stopServer.bat server1 -username admin_userid -password admin_password</td>
</tr>
<tr>
<td>WebSphere Portal</td>
<td>stopServer.bat WebSphere_Portal -username admin_userid -password admin_password</td>
</tr>
</tbody>
</table>

5. Transfer the database:

   **Note:** Important: Do not execute the database-transfer task as a background process. This might cause the task to stall.

   A. Change to the directory `wp_profile_root\ConfigEngine`.

   B. Enter the following command:

   `ConfigEngine.bat database-transfer -DWasPassword=password`

   **Note:** To select specific database domains to transfer, modify the -DTransferDomainList specified in the command to include only the domains that you want to transfer. For example, to transfer only the JCR domain you can enter the following command:

   `ConfigEngine.bat database-transfer -DTransferDomainList=jcr -DWasPassword=password`

   C. After running this task, a message is added to the log files to verify that this task was successful. Check the log files.

   If the configuration fails, verify the values in the `wkplc.properties`, `wkplc_comp.properties`, and `wkplc_dbtype.properties` files and then repeat this step.

6. After transferring the database tables, run the `dbms_stats.gather_schema_stats` command to avoid slow database response. Example:

   SQL> execute dbms_stats.gather_schema_stats(ownname=> 'jcr', cascade=> TRUE);

7. Specify the JDBC URL to connect to the cluster:

   A. Login to the WebSphere Application Server Administrator Console

   B. Navigate to Resources > JDBC Providers

   C. If there is a value in the Node field, remove it and click Apply.

   D. For each Oracle JDBC provider, repeat the following steps:

   1. Click the provider name.

   2. Select Data Sources.

   3. Click the name of the data source.

   4. Under the Oracle data source properties, modify the URL attribute according to Oracle RAC configuration:

   ```
   jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=PRIMARY_NODE_HOSTNAME)(PORT=1521))(ADDRESS=(PROTOCOL=TCP)(HOST=SECONDARY_NODE_HOSTNAME)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=DATABASE_SERVICENAME)))
   ```

   5. Save your changes

8. Change to the directory `wp_profile_root\bin`.

9. Enter the following command to start the WebSphere Portal server:

   `startServer.bat WebSphere_Portal`

---
